Perry's Chemical Engineers' Handbook

- Contents
- Conversion Factors and Mathematical Symbols
- Physical and Chemical Data
- Mathematics
- Thermodynamics
- Heat and Mass Transfer
- Fluid and Particle Dynamics
- Reaction Kinetics
- Process Control
- Process Economics
- Transport and Storage of Fluids
- Heat-Transfer Equipment
- Psychrometry, Evaporative Cooling, and Solids Drying
- Distillation
- Gas Absorption and Gas-Liquid System Design
- Liquid-Liquid Extraction Operations and Equipment
- Adsorption
- Gas-Solid Operations and Equipment
- Liquid-Solid Operations and Equipment
- Solid-Solid Operations and Equipment
- Size Reduction and Size Enlargement
- Handling of Bulk Solids and Packaging of Solids and Liquids
- Alternative Separation Processes
- Chemical Reactors
- Biochemical Engineering
- Waste Management
- Process Safety
- Energy Resources, Conversion and Utilization
- Materials of Construction
- Process Machinery Drives
- Analysis of Plant Performance
- Index

ABOUT THE EDITORS

The late **Robert H. Perry** served as chairman of the Department of Chemical Engineering at the University of Oklahoma and program director for graduate research facilities at the National Science Research Foundation. He was a consultant to various United Nations and other international organizations. From 1973 until his death in 1978 Dr. Perry devoted his time to a study of the cross impact of technologies within the next half century. The subjects under his investigation on a global basis were energy, minerals and metals, transportation and communications, medicine, food production, and the environment.

Don W. Green is Chair and the Deane E. Ackers distinguished professor of chemical and petroleum engineering and codirector of the Tertiary Oil Recovery Project at the University of Kansas in Lawrence, Kansas, where he has taught since 1964. He received his doctorate in chemical engineering in 1963 from the University of Oklahoma, where he was Dr. Perry's first doctoral student. Dr. Green has won several teaching awards at the University of Kansas, and he is a fellow of the AIChE and a distinguished member of the Society of Petroleum Engineers. He is the author of numerous articles in technical journals.

James O. Maloney is Professor Emeritus of the Department of Chemical and Petroleum Engineering, University of Kansas. He holds a Ph.D. degree in chemical engineering from Pennsylvania State University. In 1941 he began his professional career at the DuPont de Nemours Company, before joining the University of Kansas in 1945, where he taught for 40 years. He served as department chairman for nineteen years. He is a fellow of the AIChE.

Contents

For the detailed contents of any section, consult the title page of that section. See also the alphabetical index in the back of the handbook.

	Section
Conversion Factors and Mathematical Symbols *James O. Maloney*	**1**
Physical and Chemical Data *Peter E. Liley, George H. Thomson, D. G. Friend, Thomas E. Daubert, Evan Buck*	**2**
Mathematics *Bruce A. Finlayson, James F. Davis, Arthur W. Westerberg, Yoshiyuki Yamashita*	**3**
Thermodynamics *Hendrick C. Van Ness, Michael M. Abbott*	**4**
Heat and Mass Transfer *James G. Knudsen, Hoyt C. Hottel, Adel F. Sarofim, Phillip C. Wankat, Kent S. Knaebel*	**5**
Fluid and Particle Dynamics *James N. Tilton*	**6**
Reaction Kinetics *Stanley M. Walas*	**7**
Process Control *Thomas F. Edgar, Cecil L. Smith, F. Greg Shinskey, George W. Gassman, Paul J. Schafbuch, Thomas J. McAvoy, Dale E. Seborg*	**8**
Process Economics *F. A. Holland, J. K. Wilkinson*	**9**
Transport and Storage of Fluids *Meherwan P. Boyce*	**10**
Heat-Transfer Equipment *Richard L. Shilling, Kenneth J. Bell, Patrick M. Bernhagen, Thomas M. Flynn, Victor M. Goldschmidt, Predrag S. Hrnjak, F. C. Standiford, Klaus D. Timmerhaus*	**11**
Psychrometry, Evaporative Cooling, and Solids Drying *Charles G. Moyers, Glenn W. Baldwin*	**12**
Distillation *J. D. Seader, Jeffrey J. Siirola, Scott D. Barnicki*	**13**

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Gas Absorption and Gas-Liquid System Design *James R. Fair, D. E. Steinmeyer, W. R. Penny, B. B. Crocker* **14**

Liquid-Liquid Extraction Operations and Equipment *Lanny A. Robbins, Roger W. Cusack* **15**

Adsorption and Ion Exchange *M. Douglas LeVan, Giorgio Carta, Carmen M. Yon* **16**

Gas-Solid Operations and Equipment *Mel Pell, James B. Dunson* **17**

Liquid-Solid Operations and Equipment *Donald A. Dahlstrom, Richard C. Bennett, Robert G. Emmet, Peter Harriott, Tim Laros, Wallace Leung, Shelby A. Miller, Brooker Morey, James Y. Oldshue, George Priday, Charles E. Silverblatt, J. Stephen Slottee, Julian C. Smith* **18**

Solid-Solid Operations and Equipment *Kalanadh V. S. Sastry, Harrison Cooper, Richard Hogg, T. L. P. Jespen, Frank Knoll, Bhupendra Parekh, Raj K. Rajamani, Thomas Sorenson, Ionel Wechsler, Chad McCleary, David B. Todd* **19**

Size Reduction and Size Enlargement *Richard L. Snow, Terry Allen, Bryan J. Ennis, James D. Litster* **20**

Handling of Bulk Solids and Packaging of Solids and Liquids *Grantges J. Raymus* **21**

Alternative Separation Processes *Joseph D. Henry, Jr., Michael E. Prudich, William Eykamp, T. Alan Hatton, Keith P. Johnston, Richard M. Lemert, Robert Lemlich, Charles G. Moyers, John Newman, Herbert A. Pohl, Kent Pollock, Michael P. Thien* **22**

Chemical Reactors *Stanley M. Walas* **23**

Biochemical Engineering *Henry R. Bungay, Arthur E. Humphrey, George T. Tsao* **24**

Waste Management *Louis Theodore, Anthony J. Buonicore, John D. McKenna, Irwin J. Kugelman, John S. Jeris, Joseph J. Santoleri, Thomas F. McGowan* **25**

Process Safety *Stanley M. Englund, Frank T. Bodurtha, Laurence G. Britton, Daniel A. Crowl, Stanley Grossel, W. G. High, Trevor A. Kletz, Robert W. Ormsby, John E. Owens, Carl A. Schiappa, Richard Siwek, Robert E. White, David Winegardner, John L. Woodward* **26**

Energy Resources, Conversion, and Utilization *Walter F. Podolski, Shelby A. Miller, David K. Schmalzer, Anthony G. Fonseca, Vincent Conrad, Douglas E. Lowenhaupt, John Bacha, Lawrence K. Rath, Hsue-peng Loh, Edgar B. Klunder, Howard G. McIlvried, III, Gary J. Stiegel, Rameshwar D. Srivastava, Peter J. Loftus, Charles E. Benson, John M. Wheeldon, Michael Krumpelt* **27**

Materials of Construction *Oliver W. Siebert, John G. Stoecker* **28**

Process Machinery Drives *Heinz P. Bloch, R. H. Daugherty, Fred K. Geitner, Meherwan P. Boyce, Judson S. Swearingen, Eric Jennet, Michael M. Calistrat* **29**

Analysis of Plant Performance *Colin S. Howat* **30**

Index follows Section 30.

List of Contributors

Michael M. Abbott, Ph.D., Howard P. Isermann Department of Chemical Engineering, Rensselaer Polytechnic Institute; Member, American Institute of Chemical Engineers (Section 4, Thermodynamics)

Terry Allen, Ph.D., Senior Research Associate (retired), DuPont Central Research and Development (Section 20, Size Reduction and Size Enlargement)

John D. Bacha, Ph.D., Consulting Scientist, Chevron Products Company; Member, ASTM (American Society for Testing and Materials), Committee D02 on Petroleum Products and Lubricants; American Chemical Society; International Association for Stability and Handling of Liquid Fuels, Steering Committee (Section 27, Energy Resources, Conversion, and Utilization)

Glenn W. Baldwin, M.S., P.E., Staff Engineer, Union Carbide Corporation; Member, American Institute of Chemical Engineers (Section 12, Psychrometry, Evaporative Cooling, and Solids Drying)

Scott D. Barnicki, Ph.D., Senior Research Chemical Engineer, Eastman Chemical Company (Section 13, Distillation)

Kenneth J. Bell, Ph.D., P.E., Regents Professor Emeritus, School of Chemical Engineering, Oklahoma State University; Member, American Institute of Chemical Engineers (Section 11, Heat-Transfer Equipment)

Richard C. Bennett, B.S., Ch.E., Registered Professional Engineer, Illinois; Member, American Institute of Chemical Engineers (AIChE); President of Crystallization Technology, Inc.; Former President of Swenson Process Equipment, Inc. (Section 18, Liquid-Solid Operations and Equipment)

Charles E. Benson, M.Eng., M.E., Director, Combustion Technology, Arthur D. Little, Inc.; Member, American Society of Mechanical Engineers, Combustion Institute (Section 27, Energy Resources, Conversion, and Utilization)

Patrick M. Bernhagen, P.E., B.S.M.E., Senior Mechanical Engineer, Foster Wheeler USA Corporation, American Society of Mechanical Engineers (Section 11, Heat-Transfer Equipment)

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Heinz P. Bloch, P.E., B.S.M.E., M.S.M.E., Consulting Engineer, Process Machinery Consulting; American Society of Mechanical Engineers, Vibration Institute; Registered Professional Engineer (New Jersey, Texas) (Section 29, Process Machinery Drives)

Frank T. Bodurtha, Sc.D., E.I. DuPont de Nemours and Co., Inc. (retired), Wilmington, Delaware (retired); Consultant, Frank T. Bodurtha, Inc. (Section 26, Process Safety)

Meherwan P. Boyce, P.E., Ph.D., President, Boyce Engineering International; ASME Fellow; Registered Professional Engineer (Texas, Oklahoma) (Section 10, Transport and Storage of Fluids; Section 29, Process Machinery Drives)

Laurence G. Britton, Ph.D., Research Scientist, Union Carbide Corporation (Section 26, Process Safety)

Evan Buck, M.S.Ch.E., Manager, Thermophysical Property Skill Center, Central Technology, Union Carbide Corporation (Section 2, Physical and Chemical Data)

Henry R. Bungay, P.E., Ph.D., Professor of Chemical and Environmental Engineering, Rensselaer Polytechnic Institute; Member, American Institute of Chemical Engineers, American Chemical Society, American Society for Microbiology, American Society for Engineering Education, Society for General Microbiology (Section 24, Biochemical Engineering)

Anthony J. Buonicore, M.Ch.E., P.E., Diplomate AAEE, CEO, Environmental Data Resources, Inc.; Member, American Institute of Chemical Engineers, Air and Waste Management Association (Section 25, Waste Management)

Michael M. Calistrat, B.S.M.E., M.S.M.E., Owner, Michael Calistrat and Associates; Member, American Society of Mechanical Engineers (Section 29, Process Machinery Drives)

Giorgio Carta, Ph.D., Professor, Department of Chemical Engineering, University of Virginia; Member, American Institute of Chemical Engineers, American Chemical Society, International Adsorption Society (Section 16, Adsorption and Ion Exchange)

Vincent Conrad, Ph.D., Group Leader, Technical Services Development Laboratory, CONSOL, Inc.; Member, Spectroscopy Society of Pittsburgh, Society for Analytical Chemistry of Pittsburgh, Society for Applied Spectroscopy (Section 27, Energy Resources, Conversion, and Utilization)

Harrison Cooper, Ph.D., Harrison R. Cooper Systems, Inc., Salt Lake City, Utah (Section 19, Solid-Solid Operations and Equipment)

B. B. Crocker, S.M., P.E., Consulting Chemical Engineer; Fellow, American Institute of Chemical Engineers; Member, Air Pollution Control Association (Section 14, Gas Absorption and Gas-Liquid System Design)

Daniel A. Crowl, Ph.D., Professor of Chemical Engineering, Chemical Engineering Department, Michigan Technological University; Member, American Institute of Chemical Engineers, American Chemical Society (Section 26, Process Safety)

Roger W. Cusack, Vice President, Glitsch Process Systems, Inc.; Member, American Institute of Chemical Engineers (Section 15, Liquid-Liquid Extraction Operations and Equipment)

Donald A. Dahlstrom, Ph.D., Research Professor, Chemical and Fuels Engineering Department and Metallurgical Engineering Department, University of Utah; Member, National Academy of Engineering, American Institute of Chemical Engineers (AIChE), American Chemical Society (ACS), Society of Mining, Metallurgic Exploration (SME) of the American Institute of Mining, Metallurgical and Petroleum Engineers (AIME), American Society of Engineering Education (Section 18, Liquid-Solid Operations and Equipment)

Thomas E. Daubert, Ph.D., Professor, Department of Chemical Engineering, The Pennsylvania State University (Section 2, Physical and Chemical Data)

R. H. Daugherty, Ph.D., Consulting Engineer, Research Center, Reliance Electric Company; Member, Institute of Electrical and Electronics Engineers (Section 29, Process Machinery Drives)

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

James F. Davis, Ph.D., Professor of Chemical Engineering, Ohio State University (Section 3, Mathematics)

James B. Dunson, B.S., Principal Consultant, E. I. duPont de Nemours & Co.; Member American Institute of Chemical Engineers; Registered Professional Engineer (Delaware) (Section 17, Gas-Solid Operation and Equipment)

Thomas F. Edgar, Ph.D., Professor of Chemical Engineering, University of Texas, Austin, Texas (Section 8, Process Control)

Robert C. Emmet, Jr., B.S., Ch.E., Senior Process Consultant, EIMCO Process Equipment Co.; Member, American Institute of Chemical Engineers (AIChE), American Institute of Mining, Metallurgical and Petroleum Engineers (AIME), Society of Mining, Metallurgical and Exploration Engineers (SME) (Section 18, Liquid-Solid Operations and Equipment)

Stanley M. Englund, M.S., Ch.E., Fellow, American Institute of Chemical Engineers; Process Consultant, The Dow Chemical Company (retired) (Section 26, Process Safety)

Bryan J. Ennis, Ph.D., President, E&G Associates, and Adjunct Professor of Chemical Engineering, Vanderbilt University; Member and Chair of Powder Technology Programming Group of the Particle Technology Forum, American Institute of Chemical Engineers (Section 20, Size Reduction and Size Enlargement)

William Eykamp, Ph.D., Adjunct Professor of Chemical Engineering, Tufts University; Formerly President, Koch Membrane Systems; Member, American Institute of Chemical Engineers, American Chemical Society, American Association for the Advancement of Science, North American Membrane Society, European Society of Membrane Science and Technology (Section 22, Alternative Separation Processes)

James R. Fair, Ph.D., P.E., Professor of Chemical Engineering, University of Texas; National Academy of Engineering; Fellow, American Institute of Chemical Engineers; Member, American Chemical Society, American Society for Engineering Education, National Society of Professional Engineers (Section 14, Gas Absorption and Gas-Liquid System Design)

Bruce A. Finlayson, Ph.D., Rehnberg Professor and Chair, Department of Chemical Engineering, University of Washington; Member, National Academy of Engineering (Section 3, Mathematics)

Thomas M. Flynn, Ph.D., P.E., Cryogenic Engineer, President CRYOCO, Louisville, Colorado; Member, American Institute of Chemical Engineers (Section 11, Heat-Transfer Equipment)

Anthony G. Fonseca, Ph.D., Director, Coal Utilization, CONSOL, Inc.; Member, American Chemical Society, Society for Mining, Metallurgy, and Extraction (Section 27, Energy Resources, Conversion, and Utilization)

D. G. Friend, National Institutes of Standards and Technology, Boulder, Colorado (Section 2, Physical and Chemical Data)

George W. Gassman, B.S.M.E., Senior Research Specialist, Final Control Systems, Fisher Controls International, Inc., Marshalltown, Iowa (Section 8, Process Control)

Fred K. Geitner, P.Eng., B.S.M.E., M.S.M.E., Consulting Engineer, Registered Professional Engineer (Ontario, Canada) (Section 29, Process Machinery Drives)

Victor M. Goldschmidt, Ph.D., P.E., Professor of Mechanical Engineering, Purdue University, West Lafayette, Indiana (Section 11, Heat-Transfer Equipment)

Stanley Grossel, President, Process Safety & Design, Inc.; Fellow, American Institute of Chemical Engineers; Member, American Chemical Society; Member, The Combustion Institute; Member, Explosion Protection Systems Committee of NFPA (Section 26, Process Safety)

Peter Harriott, Ph.D., Professor, School of Chemical Engineering, Cornell University; Member, American Institute of Chemical Engineering, American Chemical Society (ACS) (Section 18, Liquid-Solid Operations and Equipment)

T. Alan Hatton, Ph.D., Ralph Landau Professor and Director of the David H. Koch School of Chemical Engineering Practice, Massachusetts Institute of Technology; Founding Fellow, American Institute of Medical and Biological Engineering; Member, American Institute of Chemical Engineers, American Chemical Society, International Association of Colloid and Interface Scientists, American Association for the Advancement of Science, Neutron Scattering Society of America (Section 22, Alternative Separation Processes)

Joseph D. Henry, Jr., Ph.D., P.E., Senior Fellow, Department of Engineering and Public Policy, Carnegie Mellon University; Member, American Institute of Chemical Engineers, American Society for Engineering Education (Section 22, Alternative Separation Processes)

W. G. High, C.Eng., B.Sc., F.I.Mech.E., Burgoyne Consultants Ltd., W. Yorks, England (Section 26, Process Safety)

Richard Hogg, Ph.D., Professor, Department of Mineral Engineering, The Pennsylvania State University, University Park, PA (Section 19, Solid-Solid Operations and Equipment)

F. A. Holland, D.Sc., Ph.D., Consultant in Heat Energy Recycling; Research Professor, University of Salford, England; Fellow, Institution of Chemical Engineers, London (Section 9, Process Economics)

Hoyt C. Hottel, S.M., Professor Emeritus of Chemical Engineering, Massachusetts Institute of Technology; Member, National Academy of Sciences, American Academy of Arts and Sciences, American Institute of Chemical Engineers, American Chemical Society, Combustion Institute (Section 5, Heat and Mass Transfer)

Colin S. Howat, Ph.D., P.E., John E. & Winfred E. Sharp Professor, Department of Chemical and Petroleum Engineering, University of Kansas; Member, American Institute of Chemical Engineers; Member, American Society of Engineering Education (Section 30, Analysis of Plant Performance)

Predrag S. Hrnjak, Ph.D., V.Res., Assistant Professor, University of Illinois at Urbana Champaign and Principal Investigator—U. of I. Air Conditioning and Refrigeration Center, Assistant Professor, University of Belgrade; Member, International Institute of Refrigeration, American Society of Heating, Refrigeration and Air Conditioning (Section 11, Heat-Transfer Equipment)

Arthur E. Humphrey, Ph.D., Retired, Professor of Chemical Engineering, Pennsylvania State University; Member, U.S. National Academy of Engineering, American Institute of Chemical Engineers, American Chemical Society, American Society for Microbiology (Section 24, Biochemical Engineering)

Eric Jenett, M.S.Ch.E., Manager, Process Engineering, Brown & Root, Inc.; Associate Member, AIChE, Project Management Institute; Registered Professional Engineer (Texas) (Section 29, Process Machinery Drives)

John S. Jeris, Sc.D., P.E., Professor of Environmental Engineering, Manhattan College; Environmental Consultant; Member, American Water Works Association, Water Environment Federation Section Director (Section 25, Waste Management)

T. L. P. Jespen, M.S., Min. Proc., Metallurgical Engineer, Basic, Inc., Gabbs, Nevada (Section 19, Solid-Solid Operations and Equipment)

Keith P. Johnston, Ph.D., P.E., Professor of Chemical Engineering, University of Texas (Austin); Member, American Institute of Chemical Engineers, American Chemical Society, University of Texas Separations Research Program (Section 22, Alternative Separation Processes)

Trevor A. Kletz, D.Sc., Senior Visiting Research Fellow, Department of Chemical Engineering, Loughborough University, U.K.; Fellow, American Institute of Chemical Engineers, Royal Academy of Engineers (U.K.), Institution of Chemical Engineers (U.K.), and Royal Society of Chemistry (U.K.) (Section 26, Process Safety)

Edgar B. Klunder, Ph.D., Project Manager, Energy Technology Center (Pittsburgh), U.S. Department of Energy (Section 27, Energy Resources, Conversion, and Utilization)

Preface to the Seventh Edition

Perry's has been an important source for chemical engineering information since 1934. The significant contributions of the editors who have guided preparation of the previous editions is acknowledged. These include John H. Perry (first to third editions), Robert H. Perry (fourth to sixth editions), Cecil H. Chilton (fourth and fifth editions), and Sidney D. Kirkpatrick (fourth edition). Ray Genereaux (DuPont) contributed to each of the first six editions, and Shelby Miller (Argonne National Lab) worked on the second through the seventh. The current editors directed both the sixth and seventh editions. Advances in the technology of chemical engineering have continued as we have moved toward the twenty-first century, and this edition will carry us into that century.

The *Handbook* has been reorganized. The first group of sections focuses on chemical and physical property data and the fundamentals of chemical engineering. The second and largest group of sections deals with processes, generally divided as heat transfer operations, distillation, kinetics, liquid-liquid, liquid-solid, and so on. The last group treats auxiliary information such as materials of construction, process machinery drives, waste management, and process safety. All sections have been revised and updated, and several sections are entirely new or have been extensively revised. Examples of these sections are mathematics, mass transfer, reaction kinetics, process control, transport and storage of fluids, alternative separation processes, heat-transfer equipment, chemical reactions, liquid-solid operations and equipment, process safety, and analysis of plant performance. Significant new information has also been included in the physical and chemical data sections.

Several section editors and contributors worked on this seventh edition, and these persons and their affiliations are listed as a part of the front material. Approximately one-half of the section editors are fellows of the AIChE. In addition, the following chemical engineering students at the University of Kansas assisted in the preparation of the index: Jason Canter, Pau Ying Chong, Mei Ling Chuah, Li Phoon Hor, Siew Pouy Ng, Francis J. Orzulak, Scott C. Renze, Page B. Surbaugh, and Stephen F. Weller. Shari L. Gladman and Sarah Smith provided extensive secretarial assistance.

Much of Bob Perry's work carries over into this edition and his influence is both recognized and remembered.

TABLE 1-1 SI Base and Supplementary Quantities and Units

Quantity or "dimension"	SI unit	SI unit symbol ("abbreviation"); Use roman (upright) type
Base quantity or "dimension"		
length	meter	m
mass	kilogram	kg
time	second	s
electric current	ampere	A
thermodynamic temperature	kelvin	K
amount of substance	mole*	mol
luminous intensity	candela	cd
Supplementary quantity or "dimension"		
plane angle	radian	rad
solid angle	steradian	sr

*When the mole is used, the elementary entities must be specified; they may be atoms, molecules, ions, electrons, other particles, or specified groups of such particles.

TABLE 1-2*a* Derived Units of SI that Have Special Names

Quantity	Unit	Symbol	Formula
frequency (of a periodic phenomenon)	hertz	Hz	l/s
force	newton	N	$(kg{\cdot}m)/s^2$
pressure, stress	pascal	Pa	N/m^2
energy, work, quantity of heat	joule	J	N·m
power, radiant flux	watt	W	J/s
quantity of electricity, electric charge	coulomb	C	A·s
electric potential, potential difference, electromotive force	volt	V	W/A
capacitance	farad	F	C/V
electric resistance	ohm	Ω	V/A
conductance	siemens	S	A/V
magnetic flux	weber	Wb	V·s
magnetic-flux density	tesla	T	Wb/m^2
inductance	henry	H	Wb/A
luminous flux	lumen	lm	cd·sr
illuminance	lux	lx	lm/m^2
activity (of radionuclides)	becquerel	Bq	l/s
absorbed dose	gray	Gy	J/kg

TABLE 1-2*b* Additional Common Derived Units of SI

Quantity	Unit	Symbol
acceleration	meter per second squared	m/s^2
angular acceleration	radian per second squared	rad/s^2
angular velocity	radian per second	rad/s
area	square meter	m^2
concentration (of amount of substance)	mole per cubic meter	mol/m^3
current density	ampere per square meter	A/m^2
density, mass	kilogram per cubic meter	kg/m^3
electric-charge density	coulomb per cubic meter	C/m^3
electric-field strength	volt per meter	V/m
electric-flux density	coulomb per square meter	C/m^2
energy density	joule per cubic meter	J/m^3
entropy	joule per kelvin	J/K
heat capacity	joule per kelvin	J/K
heat-flux density, irradiance	watt per square meter	W/m^2
luminance	candela per square meter	cd/m^2
magnetic-field strength	ampere per meter	A/m
molar energy	joule per mole	J/mol
molar entropy	joule per mole-kelvin	J/(mol·K)
molar-heat capacity	joule per mole-kelvin	J/(mol·K)
moment of force	newton-meter	N·m
permeability	henry per meter	H/m
permittivity	farad per meter	F/m
radiance	watt per square-meter-steradian	$W/(m^2{\cdot}sr)$
radiant intensity	watt per steradian	W/sr
specific-heat capacity	joule per kilogram-kelvin	J/(kg·K)
specific energy	joule per kilogram	J/kg
specific entropy	joule per kilogram-kelvin	J/(kg·K)
specific volume	cubic meter per kilogram	m^3/kg
surface tension	newton per meter	N/m
thermal conductivity	watt per meter-kelvin	W/(m·K)
velocity	meter per second	m/s
viscosity, dynamic	pascal-second	Pa·s
viscosity, kinematic	square meter per second	m^2/s
volume	cubic meter	m^3
wave number	1 per meter	1/m

TABLE 1-3 SI Prefixes

Multiplication factor	Prefix	Symbol
$1\ 000\ 000\ 000\ 000\ 000\ 000 = 10^{18}$	exa	E
$1\ 000\ 000\ 000\ 000\ 000 = 10^{15}$	peta	P
$1\ 000\ 000\ 000\ 000 = 10^{12}$	tera	T
$1\ 000\ 000\ 000 = 10^{9}$	giga	G
$1\ 000\ 000 = 10^{6}$	mega	M
$1\ 000 = 10^{3}$	kilo	k
$100 = 10^{2}$	hecto*	h
$10 = 10^{1}$	deka*	da
$0.1 = 10^{-1}$	deci*	d
$0.01 = 10^{-2}$	centi	c
$0.001 = 10^{-3}$	milli	m
$0.000\ 001 = 10^{-6}$	micro	μ
$0.000\ 000\ 001 = 10^{-9}$	nano	n
$0.000\ 000\ 000\ 001 = 10^{-12}$	pico	p
$0.000\ 000\ 000\ 000\ 001 = 10^{-15}$	femto	f
$0.000\ 000\ 000\ 000\ 000\ 001 = 10^{-18}$	atto	a

*Generally to be avoided.

TABLE 1-4 Conversion Factors: U.S. Customary and Commonly Used Units to SI Units (*Concluded*)

Quantity	Customary or commonly used unit	SI unit	Alternate SI unit	Conversion factor; multiply customary unit by factor to obtain SI unit	
Wavelength	Å	nm		1.0*	E − 01
Capture unit	10^{-3} cm^{-1}	m^{-1}		1.0*	E + 01
			10^{-3} cm^{-1}	1	
	m^{-1}	m^{-1}		1	
Radioactivity	Ci	Bq		3.7*	E + 10

*An asterisk indicates that the conversion factor is exact.

†Conversion factors for length, area, and volume are based on the international foot. The international foot is longer by 2 parts in 1 million than the U.S. Survey foot (land-measurement use).

NOTE: The following unit symbols are used in the table:

Unit symbol	Name	Unit symbol	Name
A	ampere	lm	lumen
a	annum (year)	lx	lux
Bq	becquerel	m	meter
C	coulomb	min	minute
cd	candela	′	minute
Ci	curie	N	newton
d	day	naut mi	U.S. nautical mile
°C	degree Celsius	Oe	oersted
°	degree	Ω	ohm
dyn	dyne	Pa	pascal
F	farad	rad	radian
fc	footcandle	r	revolution
G	gauss	S	siemens
g	gram	s	second
gr	grain	″	second
Gy	gray	sr	steradian
H	henry	St	stokes
h	hour	T	tesla
ha	hectare	t	tonne
Hz	hertz	V	volt
J	joule	W	watt
K	kelvin	Wb	weber
L, ℓ, l	liter

TABLE 1-7 Common Units and Conversion Factors*

Mass (M)
- 1 pound mass = 453.5924 grams
  - = 0.45359 kilograms
  - = 7000 grains
- 1 slug = 32.174 pounds mass
- 1 ton (short) = 2000 pounds mass
- 1 ton (long) = 2240 pounds mass
- 1 ton (metric) = 1000 kilograms
  - = 2204.62 pounds mass
- 1 pound mole = 453.59 gram moles

Length (L)
- 1 foot = 30.480 centimeters
  - = 0.3048 meters
- 1 inch = 2.54 centimeters
  - = 0.0254 meters
- 1 mile (U.S.) = 1.60935 kilometers
- 1 yard = 0.9144 meters

Area (L^2)
- 1 square foot = 929.0304 square centimeters
  - = 0.09290304 square meters
- 1 square inch = 6.4516 square centimeters
- 1 square yard = 0.836127 square meters

Volume (L^3)
- 1 cubic foot = 28,316.85 cubic centimeters
  - = 0.02831685 cubic meters
  - = 28.31685 liters
  - = 7.481 gallons (U.S.)
- 1 gallon = 3.7853 liters
  - = 231 cubic inches

Time (θ)
- 1 hour = 60 minutes
  - = 3600 seconds

Temperature (T)
- 1 centigrade or Celsius degree = 1.8 Fahrenheit degree
- Temperature, Kelvin = T°C + 273.15
- Temperature, Rankine = T°F + 459.7
- Temperature, Fahrenheit = 9/5 T°C + 32
- Temperature, centigrade or Celsius = 5/9 (T°F − 32)
- Temperature, Rankine = 1.8 T K

Force (F)
- 1 pound force = 444,822.2 dynes
  - = 4.448222 Newtons
  - = 32.174 poundals

Pressure (F/L^2)
- Normal atmospheric pressure
- 1 atm = 760 millimeters of mercury at 0°C (density 13.5951 g/cm^3)
  - = 29.921 inches of mercury at 32°F
  - = 14.696 pounds force/square inch
  - = 33.899 feet of water at 39.1°F
  - = 1.01325×10^6 dynes/square centimeter
  - = 1.01325×10^5 Newtons/square meter

Density (M/L^3)
- 1 pound mass/cubic foot = 0.01601846 grams/cubic centimeter
  - = 16.01846 kilogram/cubic meter

Energy (H or FL)
- 1 British thermal unit = 251.98 calories
  - = 1054.4 joules
  - = 777.97 foot-pounds force
  - = 10.409 liter-atmospheres
  - = 0.2930 watt-hour

Diffusivity (L^2/θ)
- 1 square foot/hour = 0.258 cm^2/s
  - = 2.58×10^{-5} m^2/s

Viscosity ($M/L\theta$)
- 1 pound mass/foot hour = 0.00413 g/cm s
  - 0.000413 kg/m s
- 1 centipoise = 0.01 poise
  - = 0.01 g/cm s
  - = 0.001 kg/m s
  - = 0.000672 lbm/ft s
  - = 0.0000209 lb_fs/ft^2

Thermal conductivity [$H/\theta L^2(T/L)$]
- 1 Btu/hr ft^2 (°F/ft) = 0.00413 cal/s cm^2 (°C/cm)
  - = 1.728 J/s m^2 (°C/m)

Heat transfer coefficient
- 1 Btu/hr ft^2 °F = 5.678 J/s m^2 °C

Heat capacity (H/MT)
- 1 Btu/lbm °F = 1 cal/g °C
  - = 4184 J/kg °C

Gas constant
- 1.987 Btu/lbm mole °R = 1.987 cal/mol K
  - = 82.057 atm cm^3/mol K
  - = 0.7302 atm ft^3/lb mole °F
  - = 10.73 (lb_f/in.^{2}) (ft^3)/lb mole °R
  - = 1545 (lb_f/ft^2) (ft^3)/lb mole °R
  - = 8.314 (N/m^2) (m^3)/mol K

Gravitational acceleration
- g = 9.8066 m/s^2
  - = 32.174 ft/s^2

NOTE: U.S. customary units; or British units, on left and SI units on right.

TABLE 1-10 United States Customary System of Weights and Measures

Linear Measure

12 inches (in) or (″) = 1 foot (ft) or (′)
3 feet = 1 yard (yd)
16.5 feet, 5.5 yards } = 1 rod (rd)
5280 feet, 320 rods } = 1 mile (mi)
1 mil = 0.001 inch

Nautical:

6080.2 feet = 1 nautical mile
6 feet = 1 fathom
120 fathoms = 1 cable length
1 knot = 1 nautical mile per hour
60 nautical miles = 1° of latitude

Square Measure

144 sq. inches (sq. in) or (in^2) or (□″) = 1 sq. foot (ft^2) or (□′)
9 sq. feet (ft^2) (□′) = 1 sq. yard (yd^2)
30.25 sq. yards = 1 sq. rod, pole, or perch
160 sq. rods = { 10 sq. chains, 43,560 sq. ft } = 1 acre
640 acres = 1 sq. mile = 1 section
1 circular inch (area of circle of 1 inch diameter) = 0.7854 sq. inch
1 sq. inch = 1.2732 circular inch
1 circular mil = area of circle of 0.001 inch diameter
1,000,000 circular mils = 1 circular inch

Circular Measure

60 seconds (″) (sec) = 1 minute (min) or (′)
60 minutes (′) = 1 degree (°)
90 degrees (°) = 1 quadrant
360 degrees (°) = 1 circumference
57.29578 degrees { = 1 radian (rad.), = 57° 17′ 44.81″

Volume Measure

Solid:

1728 cubic in (cu. in) (in^3) = 1 cubic foot (cu. ft)(ft^3)
27 cu. ft = 1 cubic yard (cu. yd)

Dry Measure:

2 pints = 1 quart
8 quarts = 1 peck
4 pecks = 1 bushel
1 United States Winchester bushel = 2150.42 cubic inches

Liquid:

4 gills = 1 pint (pt)
2 pints = 1 quart (qt)
4 quarts = 1 gallon (gal)
7.4805 gallons = 1 cubic foot

Apothecaries' Liquid:

60 minims (min. or ♏) = 1 fluid dram or drachm
8 drams (ʒ) = 1 fluid ounce
16 ounces (oz. ℥) = 1 pint

Avoirdupois Weight

16 drams = 437.5 grains = 1 ounce (oz)
16 ounces = 7000 grains = 1 pound (lb)
100 pounds = 1 hundredweight (cwt)
2000 pounds = 1 short ton: 2240 pounds = 1 long ton

Troy Weight

24 grains = 1 pennyweight (dwt)
20 pennyweights = 1 ounce (oz)
12 ounces = 1 pound (lb)

Apothecaries' Weight

20 grains (gr) = 1 scruple (℈)
3 scruples = 1 dram (ʒ)
8 drams = 1 ounce (℥)
12 ounces = 1 pound (lb)

TABLE 1-11 Temperature Conversion Formulas

°F = (°C × 5/9) + 32
°C = (°F − 32) × 5/9
°R = °F + 459.69
°K = °C + 273.15
°K = °R × 5/9

Temperature difference, ΔT
°F = °C × 9/5

NOTE: An extensive table of temperature conversions may be found in the sixth edition of the *Handbook* (Table 1-12).

TABLE 1-13 Wire and Sheet-Metal Gauges*

Values in approximate decimals of an inch

As a number of gauges are in use for various shapes and metals, it is advisable to state the thickness in thousandths when specifying gauge number.

Gauge number	American (AWG) or Brown & Sharpe (B & S) (for nonferrous wire and sheet)†	U.S. Steel Wire (Stl WG) or Washburn & Moen or Roebling or Am. Steel & Wire Co. [A. (steel) WG] (for steel wire)	Birmingham (BWG) (for steel wire) or Stubs Iron Wire (for iron or brass wire)‡	U.S. Standard (for sheet and plate metal, wrought iron)	Standard Birmingham (BG) (for sheet and hoop metal)	Imperial Standard and Wire Gauge (SWG) (British legal standard)	Gauge number
0000000	—	0.4900	—	—	0.6666	0.500	**0000000**

Metric wire gauge is 10 times the diameter in millimeters.

* Courtesy of Dr. Lewis V. Judson with I. H. Fullmer, National Bureau of Standards.

† Sometimes used for iron wire.

‡ Sometimes used for copper plate and for steel plate 12 gauge and heavier and for steel tubes.

TABLE 1-14 Fundamental Physical Constants

1 sec = 1.00273791 sidereal seconds	sec = mean solar second
g_0 = 9.80665 m/sec^2	Definition: g_0 = standard gravity
1 liter = 0.001 cu. m	
1 atm = 101,325 newtons/sq m	Definition: atm = standard atmosphere
1 mm Hg (pressure) = ($1/760$) atm	mm Hg (pressure) = standard millimeter mercury
= 133.3224 newtons/sq m	
1 int ohm = 1.000495 ± 0.000015 abs ohm	int = international; abs = absolute
1 int amp = 0.999835 ± 0.000025 abs amp	amp = ampere
1 int coul = 0.999835 ± 0.000025 abs coul	coul = coulomb
1 int volt = 1.000330 ± 0.000029 abs volt	
1 int watt = 1.000165 ± 0.000052 abs watt	
1 int joule = 1.000165 ± 0.000052 abs joule	
$T_{0°C}$ = 273.150 ± 0.010°K	Absolute temperature of the ice point, 0°C
$(PV)_{0°C}^{P=0} = (RT)_{0°C}$ = 2271.16 ± 0.04 abs joule/mole	
= 22,414.6 ± 0.4 cu. cm atm/mole	PV product for ideal gas at 0°C
= 22.4146 ± 0.0004 liter atm/mole	
R = 8.31439 ± 0.00034 abs joule/deg mole	R = gas constant per mole
= 1.98719 ± 0.00013 cal/deg mole	
= 82.0567 ± 0.0034 cu. cm atm/deg mole	
= 0.0820567 ± 0.0000034 liter atm/deg mole	
ln 10 = 2.302585	ln = natural logarithm (base e)
R ln 10 = 19.14460 ± 0.00078 abs joule/deg mole	
= 4.57567 ± 0.00030 cal/deg mole	
N = (6.02283 ± 0.0022) × 10^{23}/mole	*N = Avogadro number*
h = (6.6242 ± 0.0044) × 10^{-34} joule sec	h = Planck constant
c = (2.99776 ± 0.00008) × 10^8 m/sec	c = velocity of light
$(h^2/8\pi^2k)$ = (4.0258 ± 0.0037) × 10^{-39} g sq cm deg	Constant in rotational partition function of gases
$(h/8\pi^2c)$ = (2.7986 ± 0.0018) × 10^{-39} g cm	Constant relating wave number and moment of inertia
$Z = Nhc$ = 11.9600 ± 0.0036 abs joule cm/mole	Z = constant relating wave number and energy per mole
= 2.85851 ± 0.0009 cal cm/mole	
$(Z/R) = (hc/k) = c_2$ = 1.43847 ± 0.00045 cm deg	c_2 = second radiation constant
$\mathcal{F}$ = 96,501.2 ± 10.0 int coul/g-equiv or int joule/int volt g-equiv	$\mathcal{F}$ = Faraday constant
= 96,485.3 ± 10.0 abs coul/g-equiv or abs joule/abs volt g-equiv	
= 23,068.1 ± 2.4 cal/int volt g-equiv	
= 23,060.5 ± 2.4 cal/abs volt g-equiv	
e = (1.60199 ± 0.00060) × 10^{-19} abs coul	e = electronic charge
= (1.60199 ± 0.00060) × 10^{-20} abs emu	
= (4.80239 ± 0.00180) × 10^{-10} abs esu	
1 int electron-volt/molecule = 96,501.2 ± 10 int joule/mole	
= 23,068.1 ± 2.4 cal/mole	
1 abs electron-volt/molecule = 96,485.3 ± 10. abs joule/mole	
= 23,060.5 ± 2.4 cal/mole	
1 int electron-volt = (1.60252 ± 0.00060) × 10^{-12} erg	
1 abs electron-volt = (1.60199 ± 0.00060) × 10^{-12} erg	
hc = (1.23916 ± 0.00032) × 10^{-4} int electron-volt cm	Constant relating wave number and energy per molecule
= (1.23957 ± 0.00032) × 10^{-4} abs electron-volt cm	
k = (8.61442 ± 0.00100) × 10^{-5} int electron-volt/deg	k = Boltzmann constant
= (8.61727 ± 0.00100) × 10^{-5} abs electron-volt/deg	
= (R/N) = (1.38048 ± 0.00050) × 10^{-23} joule/deg	
1 IT cal = ($1/860$) = 0.00116279 int watt-hr	Definition of IT cal: IT = International steam tables
= 4.18605 int joule	
= 4.18674 abs joule	
= 1.000654 cal	cal = thermochemical calorie
1 cal = 4.1840 abs joule	Definition: cal = thermochemical calorie
= 4.1833 int joule	
= 41.2929 ± 0.0020 cu. cm atm	
= 0.0412929 ± 0.0000020 liter atm	
1 IT cal/g = 1.8 Btu/lb	Definition of Btu: Btu = IT British Thermal Unit
1 Btu = 251.996 IT cal	
= 0.293018 int watt-hr	
= 1054.866 int joule	
= 1055.040 abs joule	
= 252.161 cal	cal = thermochemical calorie
1 horsepower = 550 ft-lb (wt)/sec	Definition of horsepower (mechanical): lb (wt) = weight of 1 lb at standard gravity
= 745.578 int watt	
= 745.70 abs watt	Definition of in: in = U.S. inch
1 in = (1/0.3937) = 2.54 cm	ft = U.S. foot (1 ft = 12 in)
1 ft = 0.304800610 m	
1 lb = 453.5924277 g	Definition; lb = avoirdupois pound
1 gal = 231 cu. in	Definition; gal = U.S. gallon
= 0.133680555 cu. ft	
= 3.785412 × 10^{-3} cu. m	
= 3.785412 liter

CONVERSION OF VALUES FROM U.S. CUSTOMARY UNITS TO SI UNITS

American engineers are probably more familiar with the magnitude of physical entities in U.S. customary units than in SI units. Consequently, errors made in the conversion from one set of units to the other may go undetected. The following six examples will show how to convert the elements in six dimensionless groups. Proper conversions will result in the same numerical value for the dimensionless number. The dimensionless numbers used as examples are the Reynolds, Prandtl, Nusselt, Grashof, Schmidt, and Archimedes numbers.

Table 1-7 provides a number of useful conversion factors. To make a conversion of an element in U.S. customary units to SI units, one multiplies the value of the U.S. customary unit, found on the left side in the table, by the equivalent value on the right side. For example, to convert 10 British thermal units to joules, one multiplies 10 by 1054.4 to obtain 10544 joules.

In each example, the initial values of the factors are expressed in U.S. customary units, and the dimensionless value is calculated. Then the factors are converted to SI units, and the dimensionless value is recalculated. The two dimensionless values will be approximately the same. (Small variations occur due to the number of significant figures carried in the solution.)

Example 1. Calculation of a Reynolds Number

$$N_{Re} = \frac{DV\rho}{\mu}$$

U.S. customary units
- $D = 3$ in. $= 3/12$ ft
- $V = 6$ ft/s
- $\rho = 0.08$ lbm/ft^3
- $\mu = 0.015$ cp $= (0.015)(0.000672)$ lbm/ft·s

$$N_{Re} = \frac{(3/12)(6)(0.08)}{(0.015)(0.000672)} = 11{,}904$$

SI units
- $D = (3)(0.0254)$ m
- $V = (6)(0.3048)$ m/s
- $\rho = (0.08)(16.018)$ kg/m^3
- $\mu = (0.015)(0.001)$ kg/m·s

$$N_{Re} = \frac{(3 \times 0.0254)\,(6 \times 0.3048)\,(0.08 \times 16.018)}{(0.015)\,(0.001)} = 11{,}904$$

Example 2. Calculation of a Prandtl Number

$$N_{Pr} = \frac{C_p\mu}{k}$$

U.S. customary units
- $\gamma_p = 0.47$ Btu/lbm °F
- $\mu = 15$ centipoise $= (15)\,(0.000672)\,(3600)$ lbm/ft·hr
- $k = 0.065$ Btu/hr·ft^2 (°F/ft)

$$N_{Pr} = \frac{(0.47)\,(15 \times 0.000672 \times 3600)}{0.065} = 262.4$$

SI units
- $\gamma = (0.47)(4184)$ J/kg °C
- $\mu = (15)(0.001)$ kg/m·s
- $k = (0.065)(1.728)$ J/s·m^2 (°C/m)

$$N_{Pr} = \frac{(0.47)\,(4184)\,(15)\,(0.001)}{(0.065)\,(1.728)} = 262.6$$

(Difference due to rounding)

Example 3. Calculation of a Nusselt Number

$$N_{Nu} = \frac{hD}{k}$$

U.S. customary units
- $h = 200$ Btu/hr·ft^2·°F
- $D = 1.5$ in. $= 1.5/12$ ft
- $k = 0.07$ Btu/hr·ft^2 (°F/ft)

$$N_{Nu} = \frac{(200)(1.5/12)}{0.07} = 357.1$$

SI units
- $h = (200)(5.678)$ J/(s·m^2·°C)
- $D = (1.5)(0.0254)$ m
- $k = (0.07)(1.728)$ J/s·m^2 (°C/m)

$$N_{Nu} = \frac{(200)\,(5.678)\,(1.5)\,(0.0254)}{(0.07)\,(1.728)} = 357.7$$

(Difference due to rounding)

Example 4. Calculation of a Grashof Number

$$N_{Gr} = L^3\rho^2 g\beta(\Delta T)/\mu^2$$

U.S. Customary units
- $L = 3$ ft
- $\rho = 0.0725$ lbm/ft^3
- $g = 32.174$ ft/s^2
- $\beta = 0.00168$/°R
- $\Delta T = 99$ °R
- $\mu = 0.019$ centipoise $= 0.019 \times 0.000672$ lbm/ft·s $= 1.277 \times 10^{-5}$ lbm/ft·s

$$N_{Gr} = \frac{(3^3)\,(0.0725)^2(32.174)\,(0.00168)\,(99)}{(1.277 \times 10^{-5})^2} = 4.66 \times 10^9$$

SI units
- $L = (3)(0.3048) = 0.9144$ m
- $\rho = (0.0725)(16.018) = 1.1613$ kg/m^3
- $g = 9.807$ m/s^2
- $\beta = (0.00168)/(1.8) = 0.000933$/°K
- $\Delta T = (99)(1.8) = 178.2$ °K
- $\mu = (0.019)(0.001) = 1.9 \times 10^{-5}$ kg/m·s

$$N_{Gr} = \frac{(0.9144)^3(1.1613)^2(9.807)(0.000933)(178.2)}{(1.9 \times 10^{-5})^2} = 4.66 \times 10^9$$

Example 5. Calculation of a Schmidt Number

$$N_{Sc} = \frac{\mu}{\rho D}$$

U.S. customary units
- $\mu = 0.02$ centipoise $= (0.02)(2.42)$ lbm/ft·hr
- $\rho = 0.08$ lbm/ft^3
- $D = 1.0$ ft^2/hr (diffusivity)

$$N_{Sc} = \frac{(0.02)\,(2.42)}{(0.08)(1.0)} = 0.605$$

SI units
- $\mu = (0.02)(0.001)$ kg/m·s
- $\rho = (0.08)(16.02)$ kg/m^2
- $D = (1.0)(2.58 \times 10^{-5})$ m^2/s

$$N_{Sc} = \frac{(0.02)\,(0.001)}{(0.08)(16.02)(1.0)\,(2.58 \times 10^{-5})} = 0.605$$

Example 6. Calculation of an Archimedes Number

$$N_{Ar} = \frac{d^3\rho_f(\rho_p - \rho_f)g}{\mu^2}$$

U.S. customary units
- $d = 2$ mm $= 2/[(1000)(0.3048)] = 0.00656$ ft
- $\rho_f = 0.0175$ lbm/ft^3
- $\rho_p = 168.5$ lbm/ft^3
- $g = 32.174$ ft/s^2
- $\mu = 0.04$ centipoise $= 0.04 \times 0.000672 = 2.688^{-5}$ lbm/ft·s

$$N_{Ar} = \frac{(0.00656)^3\,(0.0175)\,(168.5 - 0.017)\,(32.174)}{(2.688 \times 10^{-5})^2} = 37{,}064$$

SI units
- $d = 2/1000$ m
- $\rho_p = 168.5 \times 16.02 = 2699.37$ kg/m^3
- $\rho_f = 0.0175 \times 16.02 = 0.2804$ g/m^3
- $g = 9.807$ m/s^2
- $\mu = 0.04 \times 0.001 = 4 \times 10^{-5}$ kg/m·s

$$N_{Ar} = \frac{(2/1000)^3\,(0.2804)\,(2699.37 - 0.28)\,(9.807)}{(4 \times 10^{-5})^2} = 37{,}118$$

MATHEMATICAL SYMBOLS

TABLE 1-15 Mathematical Signs, Symbols, and Abbreviations

$\pm$ ($\mp$)	plus or minus (minus or plus)
:	divided by, ratio sign
::	proportional sign
$<$	less than
$\nless$	not less than
$>$	greater than
$\ngtr$	not greater than
$\cong$	approximately equals, congruent
$\sim$	similar to
$\asymp$	equivalent to
$\neq$	not equal to
$\doteq$	approaches, is approximately equal to
$\propto$	varies as
∞	infinity
$\therefore$	therefore
$\sqrt{\ }$	square root
$\sqrt[3]{\ }$	cube root
$\sqrt[n]{\ }$	*n*th root
$\angle$	angle
$\perp$	perpendicular to
$\parallel$	parallel to
$\lvert x \rvert$	numerical value of x
log or $\log_{10}$	common logarithm or Briggsian logarithm
$\log_e$ or ln	natural logarithm or hyperbolic logarithm or Naperian logarithm
e	base (2.178) of natural system of logarithms
$a°$	an angle a degrees
a' a	prime, an angle a minutes
a'' a	double prime, an angle a seconds, a second
sin	sine
cos	cosine
tan	tangent
ctn or cot	cotangent
sec	secant
csc	cosecant
vers	versed sine
covers	coversed sine
exsec	exsecant
$\sin^{-1}$	anti sine or angle whose sine is
sinh	hyperbolic sine
cosh	hyperbolic cosine
tanh	hyperbolic tangent
$\sinh^{-1}$	anti hyperbolic sine or angle whose hyperbolic sine is
$f(x)$ or $\phi(x)$	function of x
Δx	increment of x
$\sum$	summation of
dx	differential of x
dy/dx or y'	derivative of y with respect to x
d^2y/dx^2 or y''	second derivative of y with respect to x
d^ny/dx^n	*n*th derivative of y with respect to x
$\partial y/\partial x$	partial derivative of y with respect to x
$\partial^n y/\partial x^n$	*n*th partial derivative of y with respect to x
$\dfrac{\partial^n y}{\partial x \partial y}$	*n*th partial derivative with respect to x and y
$\int$	integral of
$\int_a^b$	integral between the limits a and b
$\dot{y}$	first derivative of y with respect to time
$\ddot{y}$	second derivative of y with respect to time
Δ or ∇^2	the “Laplacian” $\left(\dfrac{\partial^2}{\partial x^2} + \dfrac{\partial^2}{\partial y^2} + \dfrac{\partial^2}{\partial z^2}\right)$
δ	sign of a variation
$\oint$	sign for integration around a closed path

TABLE 1-16 Greek Alphabet

Alpha	= Α, α = A, a	Nu	= Ν, ν = N, n
Beta	= Β, β = B, b	Xi	= Ξ, ξ = X, x
Gamma	= Γ, γ = G, g	Omicron	= Ο, ο = O, o
Delta	= Δ, δ = D, d	Pi	= Π, π = P, p
Epsilon	= Ε, ε = E, e	Rho	= Ρ, ρ = R, r
Zeta	= Ζ, ζ = Z, z	Sigma	= Σ, σ = S, s
Eta	= Η, η = E, e	Tau	= Τ, τ = T, t
Theta	= Θ, θ = Th, th	Upsilon	= Υ, υ = U, u
Iota	= Ι, ι = I, i	Phi	= Φ, φ = Ph, ph
Kappa	= Κ, κ = K, k	Chi	= Χ, χ = Ch, ch
Lambda	= Λ, λ = L, l	Psi	= Ψ, ψ = Ps, ps
Mu	= Μ, μ = M, m	Omega	= Ω, ω = O, o

Pure Component Constants . . . 2-340
Critical Temperature . . . 2-340
Critical Pressure . . . 2-340
Example 1 Estimate the Critical Temperature and Critical Pressure of 2-Butanol Using the Ambrose Method . . . 2-342
Example 2 Estimate the Critical Temperature and Critical Pressure of 2-Butanol, Which Has an Experimental Normal Boiling Point of 372.7 K . . . 2-342
Critical Volume . . . 2-344
Example 3 Estimate the Critical Volume of 2-Butanol . . . 2-344
Critical Compressibility Factor . . . 2-344
Normal Freezing Temperature (Melting Point) . . . 2-344
Normal Boiling Temperature . . . 2-344
Example 4 Estimate the Normal Boiling Point of 2-Butanol . . . 2-345
Acentric Factor . . . 2-345
Miscellaneous Characterizing Constants . . . 2-345
Vapor Pressure . . . 2-345
Correlation Methods . . . 2-345
Prediction Methods . . . 2-346
Example 5 Estimate the Vapor Pressure of 1-Butene at 98°C . . . 2-346
Example 6 Estimate the Vapor Pressure of Tetralin at 150°C . . . 2-346
Example 7 Estimate the Vapor Pressure of Thiophene at 500 K . . . 2-347
Example 8 Estimate the Vapor Pressure of Acetaldehyde at 0°C . . . 2-347
Ideal Gas Thermal Properties . . . 2-347
Heat Capacity, C_p^o . . . 2-347
Example 9 Using Eq. 2-48 to Estimate the Ideal Gas Heat Capacity of Acetone (C_3H_6O) at 600 K . . . 2-348
Enthalpy of Formation . . . 2-348
Example 10 ΔH°_{f298} of 2-Butanol . . . 2-348
Gibbs Energy of Formation . . . 2-348
Example 11 ΔG°_{f298} of Phenol . . . 2-348
Entropy of Formation . . . 2-348
Enthalpy of Vaporization and Fusion . . . 2-349
Enthalpy of Vaporization . . . 2-349
Example 12 Estimate ΔH_v of Propionaldehyde at 350 K . . . 2-350
Example 13 Estimate ΔH_v of Ethyl Acetate . . . 2-350
Example 14 Estimate ΔH_v of Ethyl Acetate at 450 K . . . 2-350
Enthalpy of Fusion . . . 2-350
Solid and Liquid Heat Capacity . . . 2-351
Solid Heat Capacity . . . 2-351
Example 15 Estimate Solid Heat Capacity of Dinenzothiophene . . . 2-351
Liquid Heat Capacity . . . 2-351
Example 16 Estimate Liquid Heat Capacity of 2-Butanol . . . 2-351
Example 17 Estimate Liquid Heat Capacity of 1,4 Pentadiene . . . 2-354
Density . . . 2-355
Correlation Methods . . . 2-355
Vapor Density Prediction . . . 2-355
Example 18 Estimate the Molar Volume of Isobutane at 155°C and 1.0 MPa Pressure . . . 2-355
Example 19 Estimate the Molar Volume of Isobutane at 155°C and 8.6 MPa Pressure . . . 2-357
Liquid Density Prediction . . . 2-358
Example 20 Estimate the Density of Saturated Liquid Propane at 0°C . . . 2-359
Example 21 Estimate the Liquid Density of *n*-Nonane at 104.5°C and 6.893 MPa Pressure . . . 2-360
Solid Density Prediction . . . 2-361
Viscosity . . . 2-361
Correlation Methods . . . 2-362
Vapor Viscosity . . . 2-362
Example 22 Estimate the Vapor Viscosity of Propane at 101.3 kPa and 80°C . . . 2-363
Example 23 Estimate the Vapor Viscosity of a Mixture of Propane and Methane . . . 2-363
Example 24 Estimate the Vapor Viscosity of Isopropyl Alcohol at 251°C and Atmospheric Pressure . . . 2-363
Example 25 Estimate the Vapor Viscosity of Carbon Dioxide at 350 K and a Total Pressure of 20 MPa . . . 2-364
Liquid Viscosity . . . 2-365
Example 26 Estimate the Liquid Viscosity of *cis*-1,4-dimethylcyclohexane at 0°C . . . 2-366
Vapor and Liquid Thermal Conductivity . . . 2-367
Gases . . . 2-367
Example 27 Estimate Thermal Conductivity for *n*-Hexane . . . 2-367
Example 28 Estimate Thermal Conductivity of Carbon Dioxide at 370 K and Low Pressure . . . 2-367
Example 29 Estimate the Thermal Conductivity of Carbon Dioxide at 370 K and 10 MPa Pressure . . . 2-368
Example 30 Estimate Thermal Conductivity of a Mixture . . . 2-368
Liquids . . . 2-368
Example 31 Estimate Thermal Conductivity of *n*-Octane at 373.15 K . . . 2-368
Example 32 Estimate Thermal Conductivity of *n*-Octane at 473.15 K . . . 2-369
Example 33 Estimate Thermal Conductivity of *n*-Butanol . . . 2-369
Example 34 Estimate the Thermal Conductivity of *n*-Propionaldehyde . . . 2-369
Example 35 Estimate Thermal Conductivity of *n*-Butanol . . . 2-369
Example 36 Estimate Thermal Conductivity of a Mixture . . . 2-370
Diffusivity . . . 2-370
Gas Diffusivity . . . 2-370
Example 37 Estimate the Diffusivity of Benzene Vapor Diffusing into Air at 30°C and 96.5 kPa Total Pressure . . . 2-370
Example 38 Estimate the Diffusivity of Hydrogen (1) in Nitrogen (2) at 60°C and 17.23 MPa . . . 2-371
Example 39 Estimate the Infinite Dilution Diffusivity of Propane (1) in Chlorobenzene (2) at 25°C . . . 2-371
Liquid Diffusivity . . . 2-371
Surface Tension . . . 2-372
Example 40 Estimate Surface Tension for Mercaptan . . . 2-372
Example 41 Estimate Surface Tension for Isobutytic Acid . . . 2-372
Example 42 Estimate Surface Tension of a Mixture . . . 2-372
Example 43 Estimate Surface Tension of a Water-Methanol Mixture . . . 2-373
Flammability Properties . . . 2-374

GENERAL REFERENCES

Considerations of reader interest, space availability, the system or systems of units employed, copyright considerations, etc., have all influenced the revision of material in previous editions for the present edition. Reference is made at numerous places to various specialized works and also, when appropriate, to more general works. A listing of general works may be useful to readers in need of further information.

PHYSICAL PROPERTIES OF PURE SUBSTANCES

TABLE 2-1 Physical Properties of the Elements and Inorganic Compounds*

Abbreviations Used in the Table

a., acid
A., specific gravity with reference to air = 1
abs., absolute
ac., acetic acid
act., acetone
al., 95 percent ethyl alcohol
alk, alkali (*i.e.,* aq. NaOH or KOH)
am., amyl (C_5H_{11})
amor., amorphous
anh., anhydrous
aq., aqueous or water
aq. reg., aqua regia
atm., atmosphere or 760 mm. of mercury pressure
bk., black
brn., brown
bz., benzene
c., cold
cb., cubic
cc, cubic centimeter
chl., chloroform
col., colorless or white
conc., concentrated
cr., crystals or crystalline
d., decomposes
D., specific gravity with reference to hydrogen = 1
d. 50, decomposes at 50°C; 50 d., melts at 50°C with decomposition
delq., deliquescent
dil., dilute
dk., dark
eff., effloresces or efflorescent
et., ethyl ether
expl., explodes
gel., gelatinous
gly., glycerol (glycerin)
gn., green
h., hot
hex., hexagonal
hyg., hygroscopic
i., insoluble
ign., ignites
lq., liquid
lt., light
m. al., methyl alcohol
mn., monoclinic
nd., needles
NH_3, liquid ammonia
NH_4OH, ammonium hydroxide solution
oct., octahedral
or., orange
pd., powder
pl., plates
pr., prisms or prismatic
pyr., pyridine
rhb., rhombic (orthorhombic)
s., soluble
satd., saturated
sl., slightly
soln., solution
subl., sublimes
sulf., sulfides
tart. a., tartaric acid
tet., tetragonal
tr., transition
tri., triclinic
trig., trigonal
v., very
vac., in vacuo
vl., violet
volt., volatile or volatilizes
wh., white
yel., yellow
∞, soluble in all proportions
<, less than
>, greater than
42±, about or near 42
$-3H_2O$, 100, loses 3 moles of water per formula weight at 100°C

Formula weights are based upon the International Atomic Weights of 1941 and are computed to the nearest hundredth.

Refractive index, where given for a uniaxial crystal, is for the ordinary (ω) ray; where given for a biaxial crystal, the index given is for the median (β) value. Unless otherwise specified, the index is given for the sodium D-line ($\lambda = 589.3$ mμ).

Specific gravity values are given at room temperatures (15° to 20°C) unless otherwise indicated by the small figures which follow the value: thus, "$5.6\frac{18°}{4}$" indicates a specific gravity of 5.6 for the substance at 18°C referred to water at 4°C. In this table the values for the specific gravity of gases are given with reference to air (A) = 1, or hydrogen (D) = 1.

Melting point is recorded in a certain case as "82 d." and in some other case as "d. 82," the distinction being made in this manner to indicate that the former is a melting point with decomposition at 82°C, while in the latter decomposition only occurs at 82°C. Where a value such as "$-2H_2O$, 82" is given it indicates loss of 2 moles of water per formula weight of the compound at a temperature of 82°C.

Boiling point is given at atmospheric pressure (760 mm. of mercury) unless otherwise indicated; thus, "$82^{15\text{ mm.}}$" indicates the boiling point is 82°C when the pressure is 15 mm.

Solubility is given in parts by weight (of the formula shown at the extreme left) per 100 parts by weight of the solvent; the small superscript indicates the temperature. In the case of gases the solubility is often expressed in some manner as "$5^{10°}$ cc" which indicates that at 10°C, 5 cc. of the gas are soluble in 100 g. of the solvent. The symbols of the common mineral acids: H_2SO_4, HNO_3, HCl, etc., represent dilute aqueous solutions of these acids. See also special tables on Solubility.

TABLE 2-2 Physical Properties of Organic Compounds*

Abbreviations Used in the Table

(A), density referred to air
al., ethyl alcohol
amor., amorphous
aq., aqua, water
brn., brown
bz., benzene
c., cubic
cc., cubic centimeter
chl., chloroform
col., colorless
cr., crystalline
d., decomposes
d-, dextrorotatory
dl-, dextro-laevorotatory
et., ethyl ether
expl., explodes
gn., green
h., hot
hex., hexagonal
i-, iso-, containing the group $(CH_3)_2CH$-
i., insoluble
ign., ignites
l-, laevorotatory
lf., leaflets
lq., liquid
m-, meta
mn., monoclinic
n-, normal
nd., needles
o-, ortho
or., orange
p-, para
pd., powder
pet., petroleum ether
pl., plates
pr., prisms
rhb., rhombic
s., soluble
s-, sec-, secondary
silv., silvery
sl., slightly
subl., sublimes
sym., symmetrical
t-, tertiary
tet., tetragonal
tri., triclinic
uns., unsymmetrical
v., very
v. s., very soluble
v. sl. s., very slightly soluble
wh., white
yel., yellow
(+), right rotation
>, greater than
<, less than
∞, infinitely

This table of the physical properties includes the organic compounds of most general interest. For the properties of other organic compounds, reference must be made to larger tables in Lange's *Handbook of Chemistry* (Handbook Publishers), *Handbook of Chemistry and Physics* (Chemical Rubber Publishing Co.), Van Nostrand's *Chemical Annual, International Critical Tables* (McGraw-Hill), and similar works.

The **molecular weights** are based on the 1941 atomic weight values. The **densities** are given for the temperature indicated and are usually referred to water at 4°C, *e.g.,* $1.028^{95/4}$ a density of 1.028 at 95°C referred to water at 4°C, the 4 being omitted when it is not clear whether the reference is to water at 4°C or at the temperature indicated by the upper figure. The melting and boiling points given have been selected from available data as probably the most accurate. The **solubility** is given in grams of the substance in 100 g. of the solvent. In the case of gases, the solubility is often expressed in some manner as "5^{10} cc." which indicates that, at 10°C, 5 cc. of the gas are soluble in 100 g. of the solvent.

Name	Synonym	Formula	Formula weight	Form and color	Specific gravity	Melting point, °C	Boiling point, °C	Solubility in 100 parts		
								Water	Alcohol	Ether
Abietic acid	sylvic acid, abietinic acid	$C_{20}H_{30}O_2$	302.44	lf.		182		i.	v. s.	v. s.

VAPOR PRESSURES OF PURE SUBSTANCES

UNITS CONVERSIONS

For this subsection, the following units conversions are applicable:

$$°F = \tfrac{9}{5}\,°C + 32.$$

To convert millimeters of mercury to pounds-force per square inch, multiply by 0.01934.

All substances are listed in alphabetical order in Table 2-6*a*.

Compiled from Daubert, T. E., R. P. Danner, H. M. Sibul, and C. C. Stebbins, DIPPR Data Compilation of Pure Compound Properties, Project 801 Sponsor Release, July, 1993, Design Institute for Physical Property Data, AIChE, New York, NY; and from Thermodynamics Research Center, "Selected Values of Properties of Hydrocarbons and Related Compounds," Thermodynamics Research Center Hydrocarbon Project, Texas A&M University, College Station, Texas (extant 1994).

Temperatures are in K; vapor pressures are in Pa.

$P_a \times 9.869233E{-}06$ = atm; $P_a \times 1.450377E{-}04$ = psia; vapor pressure = $\exp[C1 + (C2/T) + C3 \times \ln(T) + C4 \times T^{C5}]$.

[1] Decomposes violently on heating. Forms explosive peroxides with air or oxygen. Polymerizes under pressure and heat.

[2] Coefficients are hypothetical above the decomposition temperature.

[3] At the bubble point.

[4] Exhibits superfluid properties below 2.2 K.

TABLE 2-6*a* Alphabetical Index to Substances in Tables 2-6, 2-30, 2-164, 2-193, 2-196, 2-198, and 2-221

Name	Synonym	Cmpd. no.	Formula
Acetaldehyde	Ethanal	114	C_2H_4O
Acetamide		175	C_2H_5NO
Acetic acid	Ethanoic acid	136	$C_2H_4O_2$
Acetic anhydride		141	$C_4H_6O_3$
Acetone	2-Propanone	123	C_3H_6O
Acetonitrile	Methyl cyanide	177	C_2H_3N
Acetophenone	Methyl phenyl ketone	134	C_8H_8O
Acetylene		45	C_2H_2
Air		206	
Ammonia		216	NH_3
Aniline		166	C_6H_7N
Anisole	Methyl phenyl ether	111	C_7H_8O
Argon		210	Ar
Benzene		67	C_6H_6
Benzoic acid		140	$C_7H_6O_2$
Benzonitrile	Phenyl cyanide	180	C_7H_5N
Biphenyl	1,1′-Biphenyl	79	$C_{12}H_{10}$
Bromine		213	Br_2
Bromobenzene		205	C_6H_5Br
Bromoethane	Ethyl bromide	197	C_2H_5Br
Bromomethane	Methyl bromide	194	CH_3Br
1,2-Butadiene		42	C_4H_6
1,3-Butadiene		43	C_4H_6
n-Butane		4	C_4H_{10}
1-Butanol		85	$C_4H_{10}O$
2-Butanol	*sec*-Butyl alcohol	86	$C_4H_{10}O$
1-Butene		30	C_4H_8
cis-2-Butene	*Z*-2-Butene	31	C_4H_8
trans-2-Butene	*E*-2-Butene	32	C_4H_8
n-Butyl acetate		152	$C_6H_{12}O_2$
n-Butyl mercaptan	1-Butanethiol	184	$C_4H_{10}S$
sec-Butyl mercaptan	2-Butanethiol	186	$C_4H_{10}S$
Butyraldehyde	Butanal	116	C_4H_8O
n-Butyric acid		138	$C_4H_8O_2$
n-Butyronitrile	Propyl cyanide	179	C_4H_7N
Carbon dioxide		222	CO_2
Carbon disulfide		223	CS_2
Carbon monoxide		221	CO
Carbon tetrachloride	Tetrachloromethane	193	CCl_4
Chlorine		212	Cl_2
Chlorobenzene		204	C_6H_5Cl
Chloroethane	Ethyl chloride	196	C_2H_5Cl
Chloroform	Trichloromethane	192	$CHCl_3$
Chloromethane	Methyl chloride	191	CH_3Cl
1-Chloropropane	Propyl chloride	198	C_3H_7Cl
2-Chloropropane	Isopropyl chloride	199	C_3H_7Cl
o-Cresol	2-Methylphenol	98	C_7H_8O
m-Cresol	3-Methylphenol	99	C_7H_8O
p-Cresol	4-Methylphenol	100	C_7H_8O
Cumene	Isopropylbenzene	75	C_9H_{12}
Cyanogen		220	C_2N_2
Cyclohexane		60	C_6H_{12}
Cyclohexanol	Cyclohexyl alcohol	94	$C_6H_{12}O$
Cyclohexanone	Cyclohexyl ketone	133	$C_6H_{10}O$
Cyclohexene		66	C_6H_{10}
Cyclopentane		57	C_5H_{10}
Cyclopentene		64	C_5H_8
p-Cymene	*p*-Isopropyltoluene	77	$C_{10}H_{14}$
1-Decanal		122	$C_{10}H_{20}O$
n-Decane		10	$C_{10}H_{22}$
1-Decene		38	$C_{10}H_{20}$
1,1-Dichloropropane		200	$C_3H_6Cl_2$
1,2-Dichloropropane		201	$C_3H_6Cl_2$
Diethylamine		160	$C_4H_{11}N$
Diethyl ether	Ethyl ether	108	$C_4H_{10}O$
Diethyl sulfide	Ethyl sulfide	189	$C_4H_{10}S$
Diisopropylamine		165	$C_6H_{15}N$
Diisopropyl ketone	2,4-Dimethyl-3-pentanone	132	$C_7H_{14}O$
Dimethylacetylene	2-Butyne	47	C_4H_6
Dimethylamine		157	C_2H_7N
N,N-Dimethylaniline	*N,N*-Dimethylbenzamine	168	$C_8H_{11}N$
2,3-Dimethylbutane	Diisopropyl	23	C_6H_{14}
1,1-Dimethylcyclohexane		62	C_8H_{16}
Dimethyl ether	Methyl ether	101	C_2H_6O
1-Hexene		34	C_6H_{12}
1-Hexyne		51	C_6H_{10}
2-Hexyne		52	C_6H_{10}
3-Hexyne		53	C_6H_{10}
Hydrazine		217	N_2H_4
Hydrogen		207	H_2
Hydrogen bromide		226	HBr
Hydrogen chloride		225	HCl
Hydrogen cyanide		227	HCN
Hydrogen fluoride		224	HF
Hydrogen sulfide		228	H_2S
Isobutyl mercaptan	2-Methyl-1-propanethiol	185	$C_4H_{10}S$
Isobutyric acid	2-Methylpropanoic acid	139	$C_4H_8O_2$
Isooctane	2,2,4-Trimethylpentane	27	C_8H_{18}
Isoprene	2-Methyl-1,3-butadiene	44	C_5H_8
Isopropylamine		164	C_3H_9N
Mesitylene	1,3,5-Trimethylbenzene	76	C_9H_{12}
Methane		1	CH_4
Methanol	Methyl alcohol	82	CH_4O
N-Methylacetamide		176	C_3H_7NO
Methyl acetate		143	$C_3H_6O_2$
Methylacetylene		46	C_3H_4
Methylamine		156	CH_5N
N-Methylaniline		167	C_7H_9N
Methyl benzoate		153	$C_8H_8O_2$
2-Methylbutane	Isopentane	22	C_5H_{12}
2-Methyl-1-butanol		90	$C_5H_{12}O$
3-Methyl-1-butanol	Isoamyl alcohol	91	$C_5H_{12}O$
2-Methyl-1-butene		40	C_5H_{10}
2-Methyl-2-butene	Amylene	41	C_5H_{10}
Methyl butyl ether		105	$C_5H_{12}O$
3-Methyl-1-butyne		48	C_5H_8
Methyl butyrate		145	$C_5H_{10}O_2$
Methylcyclohexane		61	C_7H_{14}
Methylcyclopentane		58	C_6H_{12}
1-Methylcyclopentene		65	C_6H_{10}
Methyl ethyl ether		102	C_3H_8O
Methyl ethyl ketone	2-Butanone	124	C_4H_8O
Methyl ethyl sulfide	2-Thiabutane	188	C_3H_8S
Methyl formate		142	$C_2H_4O_2$
Methyl isobutyl ether		106	$C_5H_{12}O$
Methyl isobutyl ketone		128	$C_6H_{12}O$
Methyl isopropyl ether		104	$C_4H_{10}O$
Methyl isopropyl ketone		126	$C_5H_{10}O$
Methyl mercaptan	Methanethiol	181	CH_4S
2-Methylpentane	Isohexane	24	C_6H_{14}
3-Methyl-2-pentanone	Methyl *sec*-butyl ketone	129	$C_6H_{12}O$
2-Methylpropane	Isobutane	21	C_4H_{10}
2-Methyl-2-propanol	*tert*-Butyl alcohol	88	$C_4H_{10}O$
2-Methylpropene	Isobutene	39	C_4H_8
Methyl propionate		144	$C_4H_8O_2$
Methyl propyl ether		103	$C_4H_{10}O$
Methyl *tert*-butyl ether		107	$C_5H_{12}O$
Naphthalene		78	$C_{10}H_8$
Neon		209	Ne
Nitric oxide		219	NO
Nitrogen		215	N_2
Nitrous oxide		218	N_2O
n-Nonadecane		19	$C_{19}H_{40}$
1-Nonanal	*n*-Nonaldehyde	121	$C_9H_{18}O$
n-Nonane		9	C_9H_{20}
1-Nonene		37	C_9H_{18}
n-Octadecane		18	$C_{18}H_{38}$
1-Octanal	*n*-Octaldehyde	120	$C_8H_{16}O$
n-Octane		8	C_8H_{18}
1-Octene		36	C_8H_{16}
1-Octyne		55	C_8H_{14}
Oxygen		214	O_2
n-Pentadecane		15	$C_{15}H_{32}$
1-Pentanal	Valeraldehyde	117	$C_5H_{10}O$
n-Pentane		5	C_5H_{12}
1-Pentanol	*n*-Amyl alcohol	89	$C_5H_{12}O$

VAPOR PRESSURES OF SOLUTIONS

UNITS CONVERSIONS

For this subsection, the following units conversions are applicable:

$$°F = \tfrac{9}{5}°C + 32.$$

To convert millimeters of mercury to pounds-force per square inch, multiply by 0.01934.

To convert cubic feet to cubic meters, multiply by 0.02832.

To convert bars to pounds-force per square inch, multiply by 14.504.

To convert bars to kilopascals, multiply by 1×10^2.

TABLE 2-9 Partial Pressures of Water over Aqueous Solutions of HCl*

$\log_{10} p\text{mm} = A - B/T$, ($T$ in K), which, however, agrees only approximately with the table. The table is more nearly correct.

Partial pressure of H_2O, mmHg, °C

% HCl	*A*	*B*	0°	5°	10°	15°	20°	25°	30°	35°	40°	45°	50°	60°	70°	80°	90°	100°	110°

WATER-VAPOR CONTENT OF GASES

CHART FOR GASES AT HIGH PRESSURES

The accompanying figure is useful in determining the water-vapor content of air at high pressure in contact with liquid water.

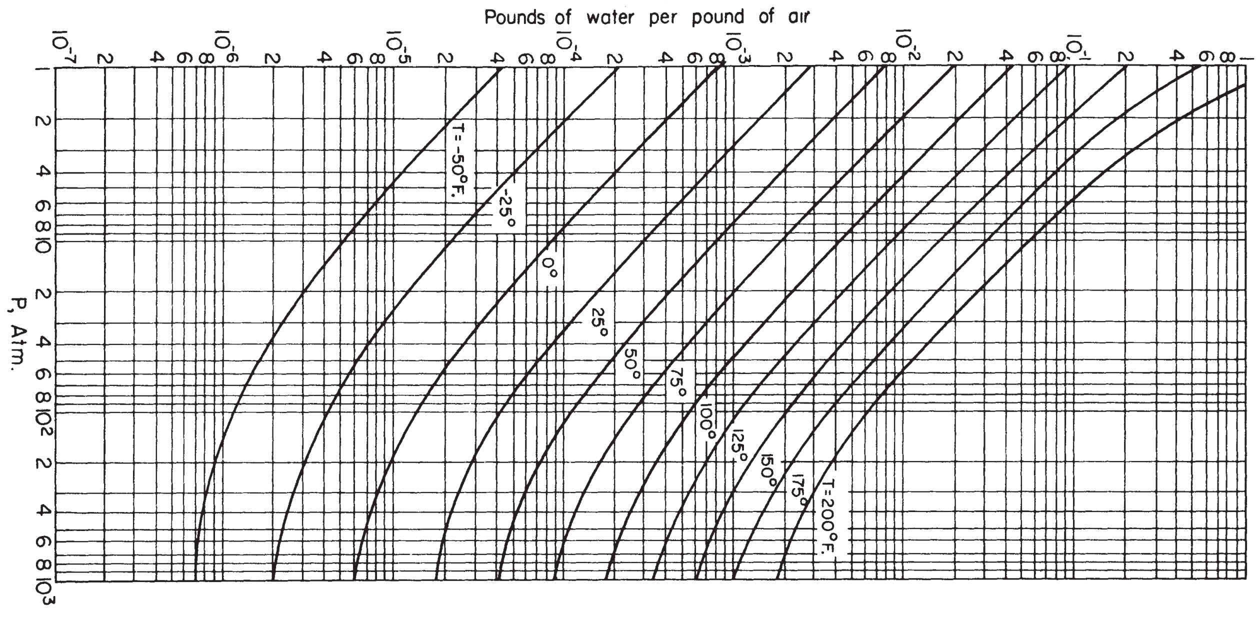

FIG. 2-4 Water content of air, °C = (°F − 32) × 5⁄9. (*Landsbaum, Dadds, and Stutzman. Reprinted from vol. 47, January 1955 issue of* Ind. Eng. Chem. [*p. 192*]. *Copyright 1955 by the American Chemical Society and reproduced by permission of the copyright owner.*)

DENSITIES OF PURE SUBSTANCES

UNITS CONVERSIONS

For this subsection, the following units conversions are applicable:

$$°F = 9/5\ °C + 32.$$

To convert kilograms per cubic meter to pounds per cubic foot, multiply by 0.06243.

TABLE 2-28 Density (kg/m³) of Water from 0 to 100°C*

*From "Water: Density at Atmospheric Pressure and Temperatures from 0 to 100°C," *Tables of Standard Handbook Data,* Standartov, Moscow, 1978. To conserve space, only a few tables of density values are given. The reader is reminded that density values may be found as the reciprocal of the specific volume values tabulated in the "Thermodynamic Properties: Tables" subsection.

*From "Mercury—Density and Thermal Expansion at Atmospheric Pressure and Temperatures from 0 to 350°C," *Tables of Standard Handbook Data,* Standartov, Moscow, 1978. The density values obtainable from those cited for the specific volume of the saturated liquid in the "Thermodynamic Properties" subsection show minor differences. No attempt was made to adjust either set.

All substances are listed in alphabetical order in Table 2-6*a.* Compiled from Daubert, T. E., R. P. Danner, H. M. Sibul, and C. C. Stebbins, DIPPR Data Compilation of Pure Compound Properties, Project 801 Sponsor Release, July, 1993, Design Institute for Physical Property Data, AIChE, New York, NY; and from Thermodynamics Research Center, "Selected Values of Properties of Hydrocarbons and Related Compounds," Thermodynamics Research Center Hydrocarbon Project, Texas A&M University, College Station, Texas (extant 1994).

Temperatures are in kelvins. Liquid densities are in kmol/m^3. Density formulas: kmol/m^3 × (mol. wt./1E+03) = g/cm^3; kmol/m^3 × (mol. wt./1.601846E+01) = lb/ft^3.

The liquid density equation is $C1/C2^{[1+(1-T/C_3)^{C_4}]}$ unless otherwise noted.

[1] The modified Rackett equation, density = $(P_c/RT_c)/ZRA^{1+[1-(T/T_c)]^{2/7}}$, was used. See Spencer, C. F., and R. P. Danner, "Improved Equation for Prediction of Saturated Liquid Density," *J. Chem. Eng. Data* **17,** 236 (1972).

[2] Decomposes violently on heating. Forms explosive peroxides with air or oxygen. Polymerizes under pressure and heat.

[3] For the hypothetical pure liquid.

[4] Exhibits superfluid properties below 2.2 K.

[5] Coefficients are hypothetical above the decomposition temperature.

[6] Lower limit is for the undercooled liquid.

[7] For the temperature range 333.15 to 403.15 K, use the coefficients: C_1 = 4.9669E+00, C_2 = 2.7788E−01, C_3 = 6.4713E+02, C_4 = 1.8740E−01. For the temperature range 403.15 to 647.13 K, use C_1 = 4.3910E+00, C_2 = 2.4870E−01, C_3 = 6.4713E+02, C_4 = 2.5340E−01.

DENSITIES OF AQUEOUS INORGANIC SOLUTIONS

UNITS AND UNITS CONVERSIONS

Densities are given in grams per cubic centimeter. To convert to pounds per cubic foot, multiply by 62.43. °F = 9⁄5 °C + 32.

DENSITIES OF AQUEOUS ORGANIC SOLUTIONS*

UNITS AND UNITS CONVERSIONS

Unless otherwise noted, densities are given in grams per cubic centimeter. To convert to pounds per cubic foot, multiply by 62.43.

$$°F = \frac{9}{5}\ °C + 32$$

From *International Critical Tables,* vol. 3, pp. 115–129. All compositions are in weight percent in vacuo. All density values are d_4^t = g/mL in vacuo.

*For gasoline and aircraft fuels see Hibbard, NACA Res. Mem. E56I21 (declassified 1958).

TABLE 2-117 Densities of Aqueous Solutions of Miscellaneous Organic Compounds*

d (resp., d_w, d_s) = density of the solution (resp., water; resp., the pure liquid solute) in g/mL; p_s (resp., p_w) = wt % of solute (resp., water) in the solution; range = range of applicability of the equation.

Section A $d = d_w + Ap_s + Bp_s^2 + Cp_s^3$

Name	Formula	t, °C	Range, p_s	A	B	C
Acetaldehyde	C_2H_4O	18	0– 30	$+0.0_{3}255$	$-0.0_{5}16$

DENSITIES OF MISCELLANEOUS MATERIALS

TABLE 2-118 Approximate Specific Gravities and Densities of Miscellaneous Solids and Liquids*

Water at 4°C and normal atmospheric pressure taken as unity. For more detailed data on any material, see the section dealing with the properties of that material.

Substance	Sp. gr.	Aver. weight lb/ft^3
Metals, Alloys, Ores		
Aluminum, cast-hammered	2.55–2.80	165
bronze	7.7	481
Brass, cast-rolled	8.4–8.7	534
Bronze, 7.9 to 14% Sn	7.4–8.9	509
phosphor	8.88	554
Copper, cast-rolled	8.8–8.95	556
ore, pyrites	4.1–4.3	262
German silver	8.58	536
Gold, cast-hammered	19.25–19.35	1205
coin (U.S.)	17.18–17.2	1073
Iridium	21.78–22.42	1383
Iron, gray cast	7.03–7.13	442
cast, pig	7.2	450
wrought	7.6–7.9	485
spiegeleisen	7.5	468
ferro-silicon	6.7–7.3	437
ore, hematite	5.2	325
ore, limonite	3.6–4.0	237
ore, magnetite	4.9–5.2	315
slag	2.5–3.0	172
Lead	11.34	710
ore, galena	7.3–7.6	465
Manganese	7.42	475
ore, pyrolusite	3.7–4.6	259
Mercury	13.6	849
Monel metal, rolled	8.97	555
Nickel	8.9	537
Platinum, cast-hammered	21.5	1330
Silver, cast-hammered	10.4–10.6	656
Steel, cold-drawn	7.83	489
machine	7.80	487
tool	7.70–7.73	481
Tin, cast-hammered	7.2–7.5	459
cassiterite	6.4–7.0	418
Tungsten	19.22	1200
Zinc, cast-rolled	6.9–7.2	440
blende	3.9–4.2	253
Various Solids		
Cereals, oats, bulk	0.51	26
barley, bulk	0.62	39
corn, rye, bulk	0.73	45
wheat, bulk	0.77	48
Cork	0.22–0.26	15
Cotton, flax, hemp	1.47–1.50	93
Fats	0.90–0.97	58
Flour, loose	0.40–0.50	28
pressed	0.70–0.80	47
Glass, common	2.40–2.80	162
plate or crown	2.45–2.72	161
crystal	2.90–3.00	184
dint	3.2–4.7	247
Hay and straw, bales	0.32	20
Leather	0.86–1.02	59
Paper	0.70–1.15	58
Potatoes, piled	0.67	44
Rubber, caoutchouc	0.92–0.96	59
goods	1.0–2.0	94
Salt, granulated, piled	0.77	48
Saltpeter	1.07	67
Starch	1.53	96
Sulfur	1.93–2.07	125
Wool	1.32	82

Substance	Sp. gr.	Aver. weight lb/ft^3
Timber, Air-dry		
Apple	0.66–0.74	44
Ash, black	0.55	34
white	0.64–0.71	42
Birch, sweet, yellow	0.71–0.72	44
Cedar, white, red	0.35	22
Cherry, wild red	0.43	27
Chestnut	0.48	30
Cypress	0.45–0.48	29
Elm, white	0.56	35
Fir, Douglas	0.48–0.55	32
balsam	0.40	25
Hemlock	0.45–0.50	29
Hickory	0.74–0.80	48
Locust	0.67–0.77	45
Mahogany	0.56–0.85	44
Maple, sugar	0.68	43
white	0.53	33
Oak, chestnut	0.74	46
live	0.87	54
red, black	0.64–0.71	42
white	0.77	48
Pine, Norway	0.55	34
Oregon	0.51	32
red	0.48	30
Southern	0.61–0.67	38–42
white	0.43	27
Poplar	0.43	27
Redwood, California	0.42	26
Spruce, white, red	0.45	28
Teak, African	0.99	62
Indian	0.66–0.88	48
Walnut, black	0.59	37
Willow	0.42–0.50	28
Various Liquids		
Alcohol, ethyl (100%)	0.789	49
methyl (100%)	0.796	50
Acid, muriatic, 40%	1.20	75
nitric, 91%	1.50	94
sulfuric, 87%	1.80	112
Chloroform	1.500	95
Ether	0.736	46
Lye, soda, 66%	1.70	106
Oils, vegetable	0.91–0.94	58
mineral, lubricants	0.88–0.94	57
Turpentine	0.861–0.867	54
Water, 4°C max. density	1.0	62.428
100°C	0.9584	59.830
ice	0.88–0.92	56
snow, fresh fallen	0.125	8
sea water	1.02–1.03	64
Ashlar Masonry		
Bluestone	2.3–2.6	153
Granite, syenite, gneiss	2.4–2.7	159
Limestone	2.1–2.8	153
Marble	2.4–2.8	162
Sandstone	2.0–2.6	143
Rubble Masonry		
Bluestone	2.2–2.5	147
Granite, syenite, gneiss	2.3–2.6	153
Limestone	2.0–2.7	147
Marble	2.3–2.7	156
Sandstone	1.9–2.5	137

Substance	Sp. gr.	Aver. weight lb/ft^3
Dry Rubble Masonry		
Granite, syenite, gneiss	1.9–2.3	130
Limestone, marble	1.9–2.1	125
Sandstone, bluestone	1.8–1.9	110
Brick Masonry		
Hard brick	1.8–2.3	128
Medium brick	1.6–2.0	112
Soft brick	1.4–1.9	103
Sand-lime brick	1.4–2.2	112
Concrete Masonry		
Cement, stone, sand	2.2–2.4	144
slag, etc.	1.9–2.3	130
cinder, etc.	1.5–1.7	100
Various Building Materials		
Ashes, cinders	0.64–0.72	40–45
Cement, Portland, loose	1.5	94
Lime, gypsum, loose	0.85–1.00	53–64
Mortar, lime, set	1.4–1.9	103
Portland cement	2.08–2.25	94–135
Portland cement	3.1–3.2	196
Slags, bank slag	1.1–1.2	67–72
bank screenings	1.5–1.9	98–117
machine slag	1.5	96
slag sand	0.8–0.9	49–55
Earth, etc., Excavated		
Clay, dry	1.0	63
damp plastic	1.76	110
and gravel, dry	1.6	100
Earth, dry, loose	1.2	76
dry, packed	1.5	95

NOTE: Above the horizontal line the condensed phase is solid; below the line, it is liquid.
*°R = 9⁄5 K.
†Polycrystalline form tabulated. Similar tables for an additional 45 elements appear in the *Handbook of Heat Transfer,* 2d ed., McGraw-Hill, New York, 1984.

SOLUBILITIES

UNITS CONVERSIONS

For this subsection, the following units conversions are applicable:

$$°F = 9⁄5 °C + 32.$$

To convert cubic centimeters to cubic feet, multiply by 3.532×10^{-5}.

To convert millimeters of mercury to pounds-force per square inch, multiply by 0.01934.

To convert grams per liter to pounds per cubic foot, multiply by 6.243×10^{-2}.

TABLE 2-120 Solubilities of Inorganic Compounds in Water at Various Temperatures*

This table shows the amount of anhydrous substance that is soluble in 100 g of water at the temperature in degrees Celsius as indicated; when the name is followed by †, the value is expressed in grams of substance in 100 cm^3 of saturated solution. Solid phase gives the hydrated form in equilibrium with the saturated solution.

	Substance	Formula	Solid phase	0°C	10°C	20°C	30°C	40°C	50°C	60°C	70°C	80°C	90°C	100°C

*By N. A. Lange. Abridged from "Table of Solubilities of Inorganic Compounds in Water at Various Temperatures" in Lange, *Handbook of Chemistry,* 10th ed., McGraw-Hill, New York, 1961. For tables of the solubility of gases in water at various temperatures, Atack (*Handbook of Chemical Data,* Reinhold, New York, 1957) gives values at closer temperature intervals, usually 1 or 5°C, than are tabulated here. For materials marked by ‡, additional data are given in tables subsequent to this one. For the solubility of various hydrocarbons in water at high pressures see *J. Chem. Eng. Data,* **4,** 212 (1959).

The H in solubility tables (2-121 to 2-144) is the proportionality constant for the expression of Henry's law, $p = Hx$, where x = mole fraction of the solute in the liquid phase; p = partial pressure of the solute in the gas phase, expressed in atmospheres; and H = a proportionality constant expressed in units of atmospheres of solute pressure in the gas phase per unit concentration of the solute in the liquid phase. (The unit of concentration of the solute in the liquid phase is moles solute per mole solution.)

TABLE 2-121 Acetylene (C_2H_2)

t, °C	0	5	10	15	20	25	30
$10^{-3} \times H$*	0.72	0.84	0.96	1.08	1.21	1.33	1.46

International Critical Tables, vol. 3, p. 260, McGraw-Hill, 1928.
*H. See footnote for Table 2-122.

TABLE 2-122 Air

t, °C	0	5	10	15	20	25	30	35
$10^{-4} \times H$*	4.32	4.88	5.49	6.07	6.64	7.20	7.71	8.23
t, °C	40	45	50	60	70	80	90	100
$10^{-4} \times H$*	8.70	9.11	9.46	10.1	10.5	10.7	10.8	10.7

International Critical Tables, vol. 3, p. 257.
*H is calculated from the absorption coefficients of O_2 and N_2, taking into consideration the correction for constant argon content.

TABLE 2-123 Ammonia (NH_3)

THERMAL EXPANSION

UNITS CONVERSIONS

For this subsection, the following units conversion is applicable:

$$°F = \tfrac{9}{5}\ °C + 32.$$

ADDITIONAL REFERENCES

The tables given under this subject are reprinted by permission from the *Smithsonian Tables.* For more detailed data on thermal expansion, see *International Critical Tables:* tabular index, vol. 3, p. 1; abrasives, vol. 2, p. 87; alloys, vol. 2, p. 463; building stones, vol. 2, p. 54; carbons, vol. 2, p. 303; elements, vol. 1, p. 102; enamels, vol. 2, p. 115; glass, vol. 2, p. 93; metals, vol. 2, p. 459; petroleums, vol. 2, p. 145; porcelains, vol. 2, pp. 70, 78; refractory materials, vol. 2, p. 83; solid insulators, vol. 2, p. 310.

THERMAL EXPANSION OF GASES

No tables of the coefficients of thermal expansion of gases are given in this edition. The coefficient at constant pressure, $1/\upsilon(\partial\upsilon/\partial T)_p$, for an ideal gas is merely the reciprocal of the absolute temperature. For a real gas or liquid, both it and the coefficient at constant volume, $1/p\ (\partial p/\partial T)_v$, should be calculated either from the equation of state or from tabulated *PVT* data.

TABLE 2-145 Linear Expansion of the Solid Elements*

C is the true expansion coefficient at the given temperature; M is the mean coefficient between given temperatures; where one temperature is given, the true coefficient at that temperature is indicated; α and β are coefficients in formula $l_t = l_0(1 + \alpha t + \beta t^2)$; l_0 is length at 0°C (unless otherwise indicated, when, if x is the reference temperature, $l_t = l_x[1 + \alpha(t - t_x) + \beta(t - t_x)^2]$; l_t is length at t°C).

TABLE 2-147 Cubical Expansion of Liquids*

If V_0 is the volume at 0°, then at t° the expansion formula is $V_t = V_0(1 + \alpha t + \beta t^2 + \gamma t^3)$. The table gives values of α, β, and γ, and of C, the true coefficient of cubical expansion at 20° for some liquids and solutions. The temperature range of the observation is Δt. Values for the coefficient of cubical expansion of liquids can be derived from the tables of specific volumes of the saturated liquid given as a function of temperature later in this section.

Liquid	Range	$\alpha \times 10^3$	$\beta \times 10^6$	$\gamma \times 10^8$	$C \times 10^8$ at 20°
Acetic acid	16–107	1.0630	0.12636	1.0876	1.071
Acetone	0–54	1.3240	3.8090	– 0.87983	1.487
Alcohol:					
Amyl	– 15–80	0.9001	0.6573	1.18458	0.902
Ethyl, 30% by volume	18–39	0.2928	10.790	–11.87	
Ethyl, 50% by volume	0–39	0.7450	1.85	0.730	
Ethyl, 99.3% by volume	27–46	1.012	2.20		1.12
Ethyl, 500 atm. pressure	0–40	0.866			
Ethyl, 3000 atm. pressure	0–40	0.524			
Methyl	0–61	1.1342	1.3635	0.8741	1.199
Benzene	11–81	1.17626	1.27776	0.80648	1.237
Bromine	0–59	1.06218	1.87714	–0.30854	1.132
Calcium chloride:					
5.8% solution	18–25	0.07878	4.2742		0.250
40.9% solution	17–24	0.42383	0.8571		0.458
Carbon disulfide	–34–60	1.13980	1.37065	1.91225	1.218
500 atm. pressure	0–50	0.940			
3000 atm. pressure	0–50	0.581			
Carbon tetrachloride	0–76	1.18384	0.89881	1.35135	1.236
Chloroform	0–63	1.10715	4.66473	– 1.74328	1.273
Ether	–15–38	1.51324	2.35918	4.00512	1.656
Glycerin		0.4853	0.4895		0.505
Hydrochloric acid, 33.2% solution	0–33	0.4460	0.215		0.455
Mercury	0–100	0.18182	0.0078		0.18186
Olive oil		0.6821	1.1405	– 0.539	0.721
Pentane	0–33	1.4646	3.09319	1.6084	1.608
Potassium chloride, 24.3% solution	16–25	0.2695	2.080		0.353
Phenol	36–157	0.8340	0.10732	0.4446	1.090
Petroleum, 0.8467 density	24–120	0.8994	1.396		0.955
Sodium chloride, 20.6% solution	0–29	0.3640	1.237		0.414
Sodium sulfate, 24% solution	11–40	0.3599	1.258		0.410
Sulfuric acid:					
10.9% solution	0–30	0.2835	2.580		0.387
100.0%	0–30	0.5758	–0.432		0.558
Turpentine	– 9–106	0.9003	1.9595	– 0.44998	0.973
Water	0–33	–0.06427	8.5053	– 6.7900	0.207

Smithsonian Tables*, Table 269. For a detailed discussion of mercury data, see Cook, *Brit. J. Appl. Phys.*, **7, 285 (1956). For data on nitrogen and argon, see Johnson (ed.), WADD-TR-60-56, 1960.

Bromoform[1] 7.7 – 50°C.

$V_t = 0.34204[1 + 0.00090411(t - 7.7) + 0.0000006766(t - 7.7)^2]$

0.34204 in the specific volume of bromoform at 7.7°C.

Glycerin[2] –62 to 0°C.

$V_t = V_0(1 + 4.83 \times 10^{-4}t - 0.49 \times 10^{-6}t^2)$

0 – 80°C.

$V_t = V_0(1 + 4.83 \times 10^{-4}t + 0.49 \times 10^{-6}t^2)$

Mercury[3] 0 – 300°C.

$V_t - V_0[1 + 10^{-8}(18153.8t + 0.7548t^2 + 0.001533t^2 + 0.00000536t^4)]$

TABLE 2-148 Cubical Expansion of Solids*

If v_2 and v_1 are the volumes at t_2 and t_1, respectively, then $v_2 = v_1(1 + C\Delta t)$, C being the coefficient of cubical expansion and Δt the temperature interval. Where only a single temperature is stated, C represents the true coefficient of cubical expansion at that temperature.

Substance	t or Δt	$C \times 10^4$
Antimony	0–100	0.3167
Beryl	0–100	0.0105
Bismuth	0–100	0.3948
Copper†	0–100	0.4998
Diamond	40	0.0354
Emerald	40	0.0168
Galena	0–100	0.558
Glass, common tube	0–100	0.276
hard	0–100	0.214
Jena, borosilicate 59 III	20–100	0.156
pure silica	0–80	0.0129
Gold	0–100	0.4411
Ice	–20 to –1	1.1250
Iron	0–100	0.3550

Sulfur, native	13.2–50.3	2.23
Tin	0–100	0.6889
Zinc†	0–100	0.8928

**Smithsonian Tables*, Table 268.

†See additional data below.

Aluminum[1] 100 – 530°C.

$V = V_0(1 + 2.16 \times 10^{-5}t + 0.95 \times 10^{-8}t^2)$

Cadmium[1] 130 – 270°C.

$V = V_0(1 + 8.04 \times 10^{-5}t + 5.9 \times 10^{-8}t^2)$

Copper[1] 110 – 300°C.

$V = V_0(1 + 1.62 \times 10^{-5}t + 0.20 \times 10^{-8}t^2)$

Colophony[2] 0 – 34°C.

$V = V_0(1 + 2.21 \times 10^{-4}t + 0.31 \times 10^{-6}t^2)$

34 – 150°C.

$V = V_{34}[1 + 7.40 \times 10^{-4}(t - 34) + 5.91 \times 10^{-6}(t - 34)^2]$

Lead[1] 100 – 280°C.

$V = V_0(1 + 1.60 \times 10^{-5}t + 3.2 \times 10^{-8}t^2)$

Shellac[2] 0 – 46°C.

$V = V_0(1 + 2.73 \times 10^{-4}t + 0.39 \times 10^{-6}t^2)$

46 – 100°C.

$V = V_{46}[1 + 13.10 \times 10^{-4}(t - 46) + 0.62 \times 10^{-6}(t - 46)^2]$

Silica (vitreous)[3] 0 – 300°C.

$V_t = V_0[1 + 10^{-8}(93.6t + 0.7776t^2 - 0.003315t^2 + 0.000005244t^4)$

Sugar (cane, amorphous)[2] 0 – 67°C.

$V_t = V_0(1 + 2.34 \times 10^{-4}t + 0.14 \times 10^{-6}t^2)$

67 – 160°C.

$V_t = V_{67}[1 + 5.02 \times 10^{-4}(t - 67) + 0.43 \times 10^{-6}(t - 67)^2]$

Zinc[1] 120 – 360°C.

$V_t = V_0(1 + 8.50 \times 10^{-5}t + 3.9 \times 10^{-8}t^2)$

JOULE-THOMSON EFFECT

UNITS CONVERSIONS

For this subsection, the following units conversions are applicable:

To convert the Joule-Thomson coefficient, μ, in degrees Celsius per atmosphere to degrees Fahrenheit per atmosphere, multiply by 1.8.

°F = 9⁄5 °C + 32; °R = 9⁄5 K

To convert bars to pounds-force per square inch, multiply by 14.504; to convert bars to kilopascals, multiply by 1×10^2.

TABLE 2-149 Additional References Available for the Joule-Thomson Coefficient

All substances are listed in alphabetical order in Table 2-6*a*.

Compiled from Daubert, T. E., R. P. Danner, H. M. Sibul, and C. C. Stebbins, DIPPR Data Compilation of Pure Compound Properties, Project 801 Sponsor Release, July, 1993, Design Institute for Physical Property Data, AIChE, New York, NY; and from Ambrose, D. "Vapour-Liquid Critical Properties", Report Chem 107, National Physical Laboratory, Teddington, UK, October, 1979.

In order to ensure thermodynamic consistency, in almost all cases these properties are calculated from T_c and the vapor pressure and liquid density correlation coefficients listed in those tables. This means that there will be slight differences between the values listed here and those in the DIPPR tables. Most of the differences are less than 1%, and almost all the rest are less than the estimated accuracy of the quantity in question.

The atomic weights used, taken from *J. Phys. Chem. Ref. Data* **22**(6), 1993, are C = 12.011, H = 1.00794, O = 15.9994, N = 14.00674, S = 32.066, F = 18.9984, Cl = 35.4527, Br = 79.904, and I = 126.90447.

The value of the gas constant, *R,* used here is 8314.51 J/(kmol·K), as given by E. R. Cohen and B. N. Taylor in *J. Phys. Chem. Ref. Data* **17,** 1988. K − 273.15 = °C; 1.8 × K − 459.67 = °F; Pa × 9.869233E-06 = atm; Pa × 1.450377E-04 = psia *j*; m^3/kmol × (1E + 03/mol. wt.) = cm^3/g; m^3/kmol × (1.601846E + 01/mol wt) = ft^3/lb.

COMPRESSIBILITIES

INTRODUCTION

The increasing ranges of pressure and temperature of interest to technology for an ever-increasing number of substances would necessitate additional tables in this subsection as well as in the subsection "Thermodynamic Properties." Space restrictions preclude this. Hence, in the present revision, an attempt was made to update the fluid-compressibility tables for selected fluids and to omit tables for other fluids. The reader is thus referred to the fourth edition for tables on miscellaneous gases at 0°C, acetylene, ammonia, ethane, ethylene, hydrogen-nitrogen mixtures, and methyl chloride. The reader is also reminded that compressibilities can be calculated from the pressure—volume (or density)—temperature tables of the subsection "Thermodynamic Properties."

UNITS CONVERSIONS

For this subsection, the following units conversions are applicable:

$$°R = \tfrac{9}{5}\ K.$$

To convert bars to pounds-force per cubic inch, multiply by 14.504.
To convert bars to kilopascals, multiply by 1×10^2.

*Calculated from PVT values tabulated in Rabinovich (ed.), *Thermophysical Properties of Neon, Argon, Krypton and Xenon,* Standards Press, Moscow, 1976. This book was published in English translation by Hemisphere, New York, 1988 (604 pp.).

TABLE 2-188 Compressibilities of Liquids*

At the constant temperature T, the compressibility $\beta = (1/\bar{V}_0)(dV/dP)$. In general as P increases, β decreases rapidly at first and then slowly; the change of β with T is large at low pressures but very small at pressures above 1000 to 2000 megabars. 1 megabar = 0.987 atm. = 10^6 dynes/cm^2 based upon the older usage, 1 bar = 1 dyne/cm^2. The use of the bar as a pressure unit is not encouraged.

Substance	Temp., °C	Pressure, megabars	Compressibility per megabar $\beta \times 10^6$	Substance	Temp., °C	Pressure, megabars	Compressibility per megabar $\beta \times 10^6$	Substance	Temp., °C	Pressure, megabars	Compressibility per megabar $\beta \times 10^6$

TABLE 2-189 Compressibilities of Solids

Many data on the compressibility of solids obtained prior to 1926 are contained in Gruneisen, *Handbuch der Physik,* vol. 10, Springer, Berlin, 1926, pp. 1–52; also available as translation, NASA RE 2-18-59W, 1959. See also Tables 271, 273, 276, 278, and other material in *Smithsonian Physical Tables,* 9th ed., 1954. For a review of high-pressure work to 1946, see Bridgman, *Rev. Mod. Phys.,* **18,** 1 (1946).

LATENT HEATS

UNITS CONVERSIONS

For this subsection, the following units conversions are applicable:

$$°F = \tfrac{9}{5}\,°C + 32.$$

To convert calories per gram-mole to British thermal units per pound-mole, multiply by 1.799; to convert calories per gram to British thermal units per pound, multiply by 1.799.

To convert millimeters of mercury to pounds-force per square inch, multiply by 1.934×10^{-2}.

TABLE 2-192 Heats of Fusion of Organic Compounds

The values for the hydrocarbons are from the tables of the American Petroleum Institute Research Project 44 at the National Bureau of Standards, with some from Parks and Huffman, *Ind. Eng. Chem.,* **23,** 1138 (1931).

The values for the nonhydrocarbon compounds were recalculated from data in *International Critical Tables,* vol. 5.

Hydrocarbon compounds	Formula	mp, °C	Heat of fusion, cal/g
Paraffins			
Methane	CH_4	−182.48	14.03
Ethane	C_2H_6	−183.23	22.712
Propane	C_3H_8	−187.65	19.100
n-Butane	C_4H_{10}	−138.33	19.167
2-Methylpropane	C_4H_{10}	−159.60	18.668
n-Pentane	C_5H_{12}	−129.723	27.874
2-Methylbutane	C_5H_{12}	−159.890	17.076
2,2-Dimethylpropane	C_5H_{12}	−16.6	10.786
n-Hexane	C_6H_{14}	−95.320	36.138
2-Methylpentane	C_6H_{14}	−153.680	17.407
2,2-Dimethylbutane	C_6H_{14}	−99.73	1.607
2,3-Dimethylbutane	C_6H_{14}	−128.41	2.251

All substances are listed in alphabetical order in Table 2-6*a*.

Compiled from Daubert, T. E., R. P. Danner, H. M. Sibul, and C. C. Stebbins, DIPPR Data Compilation of Pure Compound Properties, Project 801 Sponsor Release, July, 1993, Design Institute for Physical Property Data, AIChE, New York, NY; and from Thermodynamics Research Center, "Selected Values of Properties of Hydrocarbons and Related Compounds," Thermodynamics Research Center Hydrocarbon Project, Texas A&M University, College Station, Texas (extant 1994).

Temperatures are expressed in kelvins; heats of vaporization, in J/kmol.

J/kmol × 2.390E−04 = cal/gmol; J/kmol × 4.302106E−04 = Btu/lbmol.

The heat of vaporization equation used is $\Delta H_v = C1 \times (1 - T_r)^{C2 + C3 \times T_r + C4 \times T_r \times T_r}$. T_r is the reduced temperature, T/T_c.

[1] Coefficients are hypothetical; compound *decomposes violently* on heating.

[2] For the monomer.

[3] Equation coefficients are hypothetical above the decomposition temperature.

SPECIFIC HEATS OF PURE COMPOUNDS

UNITS CONVERSIONS

For this subsection, the following units conversions are applicable:

°F = 9⁄5 °C + 32
°F = 1.8 K

To convert calories per gram-kelvin to British thermal units per pound-degree Rankine, multiply by 1.0; to convert calories per gram-mole-kelvin to British thermal units per pound-mole-degree Rankine, multiply by 1.0.

To convert kilojoules per kilogram-kelvin to British thermal units per pound-degree Rankine, multiply by 0.2388.

ADDITIONAL REFERENCES

Additional data are contained in the subsection "Thermodynamic Properties." Data on water are also contained in that subsection. Additional tables for water are found in Eng. Sci. Data Item 68008, 251 Regent Street, London, England, which contains about 5000 values from 1 to 1000 bar, 0 to 1500°C.

*From Kelley, U.S. Bur. Mines Bull. 371, 1934. For a revision see Kelley, U.S. Bur. Mines Bull. 477, 1948. Data for many elements and compounds are given by Johnson (ed.), WADD-TR-60-56, 1960, for cryogenic temperatures. Tabulated data for gases can be obtained from many of the references cited in the "Thermodynamic Properties" subsection and other tables in this section. Thinh, Duran, et al., *Hydrocarbon Process.*, **50,** 98 (January 1971), review previous equation fits and give newer fits for 408 hydrocarbons and related compounds. Later publications include Duran, Thinh, et al., *Hydrocarbon Process.*, **55,** 153 (August 1976); Thompson, *J. Chem. Eng. Data,* **22**(4), 431 (1977); and Passut and Danner, *Ind. Eng. Chem. Process Des. Dev.*, **11,** 543 (1972); **13,** 193 (1974).

†The symbols in this column have the following meaning; *c,* crystal; *l,* liquid; *g,* gas; *gls,* glass.

All substances are listed in alphabetical order in Table 2-6*a.*

Compiled from Daubert, T. E., R. P. Danner, H. M. Sibul, and C. C. Stebbins, DIPPR Data Compilation of Pure Compound Properties, Project 801 Sponsor Release, July, 1993, Design Institute for Physical Property Data, AIChE, New York, NY; and from Thermodynamics Research Center, "Selected Values of Properties of Hydrocarbons and Related Compounds," Thermodynamics Research Center Hydrocarbon Project, Texas A&M University, College Station, Texas (extant 1994).

Temperatures are expressed in kelvins; liquid heat capacities are in J/kmol-K.

J/(kmol·K) × 2.390E–04 = cal/(gmol·°C); J/(kmol·K) × 2.390059E–04 = Btu/(lbmol·°F).

Equation 1, heat capacity $= C1 + C2 \times T + C3 \times T^2 + C4 \times T^3 + C5 \times T^4$, should be used except as otherwise specified.

Equation 2 is heat capacity $= C1^2/t + C2 - (2 \times C1 \times C3)t - (C1 \times C4)t^2 - (C3^{2/3})t^3 - (C3 \times C4/2)t^4 - (C4^{2/5})t^5$. $t = (1 - T_r)$ and T_r is the reduced temperature, T/T_c.

[1] Coefficients are for the monomer and are hypothetical above 473 K.

[2] For the saturated heat capacity.

[3] Coefficients are hypothetical; compound *decomposes violently* on heating.

[4] Coefficients are hypothetical and are based on predicted data.

[5] Coefficients are hypothetical.

[6] Exhibits superfluid properties below 2.2 K.

All substances are listed in alphabetical order in Table 2-6*a*.

Compiled from Daubert, T. E., R. P. Danner, H. M. Sibul, and C. C. Stebbins, DIPPR Data Compilation of Pure Compound Properties, Project 801 Sponsor Release, July, 1993, Design Institute for Physical Property Data, AIChE, New York, NY; and from Thermodynamics Research Center, "Selected Values of Properties of Hydrocarbons and Related Compounds," Thermodynamics Research Center Hydrocarbon Project, Texas A&M University, College Station, Texas (extant 1994).

Temperatures are expressed in kelvins; heat capacities, in J/kmol-K.

J/(kmol·K) × 2.390E−04 = cal/(gmol·°C); J/(kmol·K) × 2.390059E−04 = Btu/(lbmol·°F).

Use heat capacity $= C1 + C2\left[\frac{C3}{T}\Big/\sinh\left(\frac{C3}{T}\right)\right]^2 + C4\left[\frac{C5}{T}\Big/\cosh\left(\frac{C5}{T}\right)\right]^2$ unless otherwise specified.

Equation 2 is heat capacity $= C1 + C2 \times T + C3 \times T^2 + C4 \times T^3 + C5 \times T^4$.

Equation 3 is heat capacity $= C1 + C2 \times \ln T + C3/T + C4 \times T$.

[1] For the monomer. Monomer and dimer are in equilibrium below 600 K.

[2] For the monomer.

[3] For equilibrium mixture of *ortho* and *para* hydrogen.

SPECIFIC HEATS OF AQUEOUS SOLUTIONS

UNITS CONVERSIONS

For this subsection, the following units conversions are applicable:

$$°F = {}^9\!/_5\ °C + 32.$$

To convert calories per gram-degree Celsius to British thermal units per pound-degree Fahrenheit, multiply by 1.0.

ADDITIONAL REFERENCES

TABLE 2-220 Heats and Free Energies of Formation of Inorganic Compounds

The values given in the following table for the heats and free energies of formation of inorganic compounds are derived from (*a*) Bichowsky and Rossini, "Thermochemistry of the Chemical Substances," Reinhold, New York, 1936; (*b*) Latimer, "Oxidation States of the Elements and Their Potentials in Aqueous Solution," Prentice-Hall, New York, 1938; (*c*) the tables of the American Petroleum Institute Research Project 44 at the National Bureau of Standards; and (*d*) the tables of Selected Values of Chemical Thermodynamic Properties of the National Bureau of Standards. The reader is referred to the preceding books and tables for additional details as to methods of calculation, standard states, and so on.

† The physical state is indicated as follows: *c,* crystal (solid); *l,* liquid; *g,* gas; *gls,* glass or solid supercooled liquid; *aq,* in aqueous solution. A number following the symbol *aq* applies only to the values of the heats of formation (not to those of free energies of formation); and indicates the number of moles of water per mole of solute; when no number is given, the solution is understood to be dilute. For the free energy of formation of a substance in aqueous solution, the concentration is always that of the hypothetical solution of unit molality.

‡ The increment in heat content, Δ*H,* in the reaction of forming the given substance from its elements in their standard states. When Δ*H* is negative, heat is evolved in the process, and, when positive, heat is absorbed.

§ The heat of solution in water of a given solid, liquid, or gaseous compound is given by the difference in the value for the heat of formation of the given compound in the solid, liquid, or gaseous state and its heat of formation in aqueous solution. The following two examples serve as an illustration of the procedure: (1) For NaCl(*c*) and NaCl(*aq,* 400H_2O), the values of Δ*H*(formation) are, respectively, −98.321 and −97.324 kg-cal per mole. Subtraction of the first value from the second gives Δ*H* = 0.998 kg-cal per mole for the reaction of dissolving crystalline sodium chloride in 400 moles of water. When this process occurs at a constant pressure of 1 atm, 0.998 kg-cal of energy are absorbed. (2) For HCl(*g*) and HCl(*aq,* 400H_2O), the values for Δ*H*(formation) are, respectively, −22.06 and −39.85 kg-cal per mole. Subtraction of the first from the second gives Δ*H* = −17.79 kg-cal per mole for the reaction of dissolving gaseous hydrogen chloride in 400 moles of water. At a constant pressure of 1 atm, 17.79 kg-cal of energy are evolved in this process.

‖ The increment in the free energy, Δ*F,* in the reaction of forming the given substance in its standard state from its elements in their standard states. The standard states are: for a gas, fugacity (approximately equal to the pressure) of 1 atm; for a pure liquid or solid, the substance at a pressure of 1 atm; for a substance in aqueous solution, the hypothetical solution of unit molality, which has all the properties of the infinitely dilute solution except the property of concentration.

¶ The free energy of solution of a given substance from its normal standard state as a solid, liquid, or gas to the hypothetical one molal state in aqueous solution may be calculated in a manner similar to that described in footnote § for calculating the heat of solution.

TABLE 2-221 Enthalpies and Gibbs Energies of Formation, Entropies, and Net Enthalpies of Combustion of Inorganic and Organic Compounds (*Concluded*)

Cmpd. no.	Name	Formula	CAS no.	Mol wt	Ideal gas enthalpy of formation, J/kmol × 1E-07	Ideal gas Gibbs energy of formation, J/kmol × 1E-07	Ideal gas entropy, J/(kmol·K) × 1E-05	Standard net enthalpy of combustion, J/kmol × 1E-09
228	Hydrogen sulfide	H_2S	7783064	34.082	−2.0630	−3.3440	2.0560	−0.5180
229	Sulfur dioxide	SO_2	7446095	64.065	−29.6840	−30.0120	2.4810	0
230	Sulfur trioxide	SO_3	7446119	80.064	−39.5720	−37.0950	2.5651	0.0989
231	Water	H_2O	7732185	18.015	−24.1814	−22.8590	1.8872	0

All substances are listed in alphabetical order in Table 2-6*a*.

Compiled from Daubert, T. E., R. P. Danner, H. M. Sibul, and C. C. Stebbins, DIPPR Data Compilation of Pure Compound Properties, Project 801 Sponsor Release, July, 1993, Design Institute for Physical Property Data, AIChE, New York, NY; and from Thermodynamics Research Center, "Selected Values of Properties of Hydrocarbons and Related Compounds," Thermodynamics Research Center Hydrocarbon Project, Texas A&M University, College Station, Texas (extant 1994).

The compounds are considered to be formed from the elements in their standard states at 298.15 K and 101,325 P_a. These include C (graphite) and S (rhombic).

Enthalpy of combustion is the net value for the compound in its standard state at 298.15K and 101,325 Pa.

Products of combustion are taken to be CO_2 (gas), H_2O (gas), F_2 (gas), Cl_2 (gas), Br_2 (gas), I_2 (gas), SO_2 (gas), N_2 (gas), H_3PO_4 (solid), and SiO_2 (crystobalite).

J/kmol × 2.390E-04 = cal/gmol; J/kmol × 4.302106E-04 = Btu/lbmol.

J/(kmol·K) × 2.390E-04 = cal/(gmol·°C); J/(kmol·K) × 2.390059E-04 = Btu/(lbmol·°F).

Usually rounded off from JANAF Thermochemical Tables, NSRDS-NBS-37, 1971 (1141 pp.). Equilibrium constants can be calculated by combining Δh_f° values from Table 2-221, $h_T - h_{298}$ from Table 2-222, and $s°$ values from the above, using the formula $\ln k_p = -\Delta G/(RT)$, where $\Delta G = \Delta h_f^\circ + (h_T - h_{298}) - Ts^\circ$.

HEATS OF SOLUTION

TABLE 2-224 Heats of Solution of Inorganic Compounds in Water

Heat evolved, in kilogram-calories per gram formula weight, on solution in water at 18°C. Computed from data in Bichowsky and Rossini, *Thermochemistry of Chemical Substances,* Reinhold, New York, 1936.

Substance	Dilution*	Formula	Heat, kg-cal/g-mole
Aluminum bromide	aq	$AlBr_3$	+85.3
chloride	600	$AlCl_3$	+77.9
	600	$AlCl_3 \cdot 6H_2O$	+13.2
fluoride	aq	AlF_3	+31
	aq	$AlF_3 \cdot \frac{1}{2}H_2O$	+19.0
	aq	$AlF_3 \cdot 3\frac{1}{2}H_2O$	−1.7
iodide	aq	AlI_3	+89.0
sulfate	aq	$Al_2(SO_4)_3$	+126
	aq	$Al_2(SO_4)_3 \cdot 6H_2O$	+56.2
	aq	$Al_2(SO_4)_3 \cdot 18H_2O$	+6.7
Ammonium bromide	aq	NH_4Br	−4.45
chloride	∞	NH_4Cl	−3.82
chromate	aq	$(NH_4)_2CrO_4$	−5.82
dichromate	600	$(NH_4)_2Cr_2O_7$	−12.9

THERMODYNAMIC PROPERTIES

EXPLANATION OF TABLES

The following subsection presents information on the thermodynamic properties of a number of fluids. In some cases transport properties are also included.

Notation

c_p = specific heat
e = specific internal energy
h = enthalpy
k = thermal conductivity
p = pressure
s = specific entropy
t = temperature
T = absolute temperature
u = specific internal energy
μ = viscosity
v = specific volume
f = subscript denoting saturated liquid
g = subscript denoting saturated vapor

UNITS CONVERSIONS

For this subsection, the following units conversions are applicable:

c_p, specific heat: To convert kilojoules per kilogram-kelvin to British thermal units per pound–degree Fahrenheit, multiply by 0.23885.

e, internal energy: To convert kilojoules per kilogram to British thermal units per pound, multiply by 0.42992.

g, gravity acceleration: To convert meters per second squared to feet per second squared, multiply by 3.2808.

h, enthalpy: To convert kilojoules per kilogram to British thermal units per pound, multiply by 0.42992.

k, thermal conductivity: To convert watts per meter-kelvin to British thermal unit–feet per hour–square foot–degree Fahrenheit, multiply by 0.57779.

p, pressure: To convert bars to kilopascals, multiply by 1×10^2; to convert bars to pounds-force per square inch, multiply by 14.504; and to convert millimeters of mercury to pounds-force per square inch, multiply by 0.01934.

s, entropy: to convert kilojoules per kilogram-kelvin to British thermal units per pound–degree Rankine, multiply by 0.23885.

t, temperature: °F = 9⁄5 °C + 32.

T, absolute temperature: °R = 9⁄5 K.

u, internal energy: to convert kilojoules per kilogram to British thermal units per pound, multiply by 0.42992.

μ, viscosity: to convert pascal-seconds to pound-force–seconds per square foot, multiply by 0.020885; to convert pascal-seconds to c_p, multiply by 1000.

v, specific volume: to convert cubic meters per kilogram to cubic feet per pound, multiply by 16.018.

ρ, density: to convert kilograms per cubic meter to pounds per cubic foot, multiply by 0.062428.

Copyrighted material. Reproduced by permission. Vapor properties extracted or converted from Vasserman, Kazavchinskii, and Rabinovich, *Thermophysical Properties of Air and Its Components,* Nauka, Moscow, 1966, and NBS-NSF transl. TT 70-50095, 1971. Copyrighted material. Reproduced by permission. Note that on pages 150–151 of the TT 69-55092 publication certain values of TT 70-50095 were adjusted. As a complete retabulation was not given, the tables here are based upon the two separate publications, as indicated. See also Table 2-235 for the argon-oxygen-nitrogen equilibrium data. c = critical point. The notation 1.040.–3 signifies 1.040×10^{-3}.

*For sources, units, and remarks, see Table 2-228. v = specific volume, m^3/kg; h = specific enthalpy, kJ/kg; s = specific entropy, kJ/(kg·K); c_p = specific heat at constant pressure, kJ/(kg·K); μ = viscosity, 10^{-4} Pa·s; and k = thermal conductivity, W/(m·K). For specific heat ratio, see Table 2-200; for Prandtl number, see Table 2-369.

*Values rounded off from Chappell and Cockshutt, Nat. Res. Counc. Can. Rep. NRC LR 759 (NRC No. 14300), 1974. This source tabulates values of seven thermodynamic functions at 1-K increments from 200 to 2200 K in SI units and at other increments for two other unit systems. An earlier report (NRC LR 381, 1963) gives a more detailed description of an earlier fitting from 200 to 1400 K. In the above table h = specific enthalpy, kJ/kg, and $\Psi_2 - \Psi_1 = \log_{10} (P_2/P_1)_s$ for an isentrope. In terms of the Keenan and Kaye function ϕ, $\Psi = (\log_{10} e/R) \cdot \phi$.

TABLE 2-231 Air

Other tables include Stewart, R. B., S. G. Penoncello, et al., University of Idaho CATS report, 85-5, 1985 (0.1–700 bar, 85–750 K), and a revision is in process of publication. Tables including reactions with hydrocarbons include Gordon, S., NASA Techn. Paper 1907, 4 vols., 1982. See also Gupta, R. N., K-P. Lee, et al., NASA RP 1232, 1990 (89 pp.) and RP 1260, 1991 (75 pp.). Analytic expressions for high temperatures were given by Matsuzaki, R., *Jap. J. Appl. Phys.,* **21,** 7 (1982): 1009–1013 and Japanese National Aerospace Laboratory report NAL TR 671, 1981 (45 pp.). Functions from 1500 to 15000 K were tabulated by Hilsenrath, J. and M. Klein, AEDC-TR-65-58 = AD 612 301, 1965 (333 pp.). Tables from 10000 to 10,000,000 K were authored by Gilmore, F. R., Lockheed rept. 3-27-67-1, vol 1., 1967 (340 pp.), also published as *Radiative Properties of Air,* IFI/Plenum, New York, 1969 (648 pp.). Saturation and superheat tables and a chart to 7000 psia, 660°R appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

AIR, MOIST

An ASHRAE publication, *Thermodynamic Properties of Dry Air and Water and S. I. Psychrometric Charts,* 1983 (360 pp.), extensively reviews moist air properties. Gandiduson, P., *Chem. Eng.,* Oct. 29, 1984 gives on page 118 a nomograph from 50 to 120°F, while equations in SI units were given by Nelson, B., *Chem. Eng. Progr.* **76,** 5 (May 1980): 83–85. Liley, P. E., *2000 Solved Problems in M.E. Thermodynamics,* McGraw-Hill, New York, 1989, gives four simple equations with which most calculations can be made. Devres, Y.O., *Appl. Energy* **48** (1994): 1–18 gives equations with which three known properties can be used to determine four others. Klappert, M. T. and G. F. Schilling, Rand RM-4244-PR = AD 604 856, 1984 (40 pp.) gives tables from 100 to 270 K, while programs from −60 to 2°F are given by Sando, F. A., *ASHRAE Trans.,* **96,** 2 (1990): 299–308.

Viscosity references include Kestin, J. and J. H. Whitelaw, *Int. J. Ht. Mass Transf.* **7,** 11 (1964): 1245–1255; Studnokov, E. L., *Inz.-Fiz. Zhur.* **19,** 2 (1970): 338–340; Hochramer, D. and F. Munczak, *Setzb. Ost. Acad. Wiss II* **175,** 10 (1966): 540–550. For thermal conductivity see, for instance, Mason, E. A. and L. Monchick, *Humidity and Moisture Control in Science and Industry,* Reinhold, New York, 1965 (257–272).

*P, v, h, and s values condensed from *ASHRAE Handbook, 1981: Fundamentals.* Copyright 1981 by the American Society of Heating, Refrigerating and Air Conditioning Engineers, Inc., and reproduced by permission of the copyright owner. c_p, μ, and k values are interpolated and converted from *Thermophysical Properties of Refrigerants,* ASHRAE, New York, 1976. t = triple point; c = critical point. The notation 1.327.–3 signifies 1.327×10^{-3}. At 195.5 K, the viscosity of the saturated liquid is 4.25×10^{-4} Pa·s.

Most recent tabulations of ammonia properties are based upon the extensive tabulation to 5000 bar, 750 K of Haar, L. and J. S. Gallagher, *J. Phys. Chem. Ref. Data,* **7,** 3 (1978): 635–792, which does, however, neglect dissociation. For tables to 70,000 psia, 920°F, see Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). A chart in fps units corresponding with these tables appears on page 17.34 of the ASHRAE 1989 *Fundamentals Handbook.*

Simmons, A. L., C. E. Miller III, et al., *Tables and Charts of Equilibrium Thermodynamic Properties of Ammonia for Temperatures from 500 to 50000 K,* NASA SP 3099, 1976 (255 pp.), tabulates ρ, h, s, c_p, c_v, Z, and so on, from 0.01 to 400 bar and also 18 species of decomposition products.

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives material for integral degrees Celsius with temperatures on the ITS 90 scale for saturation temperatures from −77.66 to 132.22 °C. The same diagram reproduced here appears in that source.

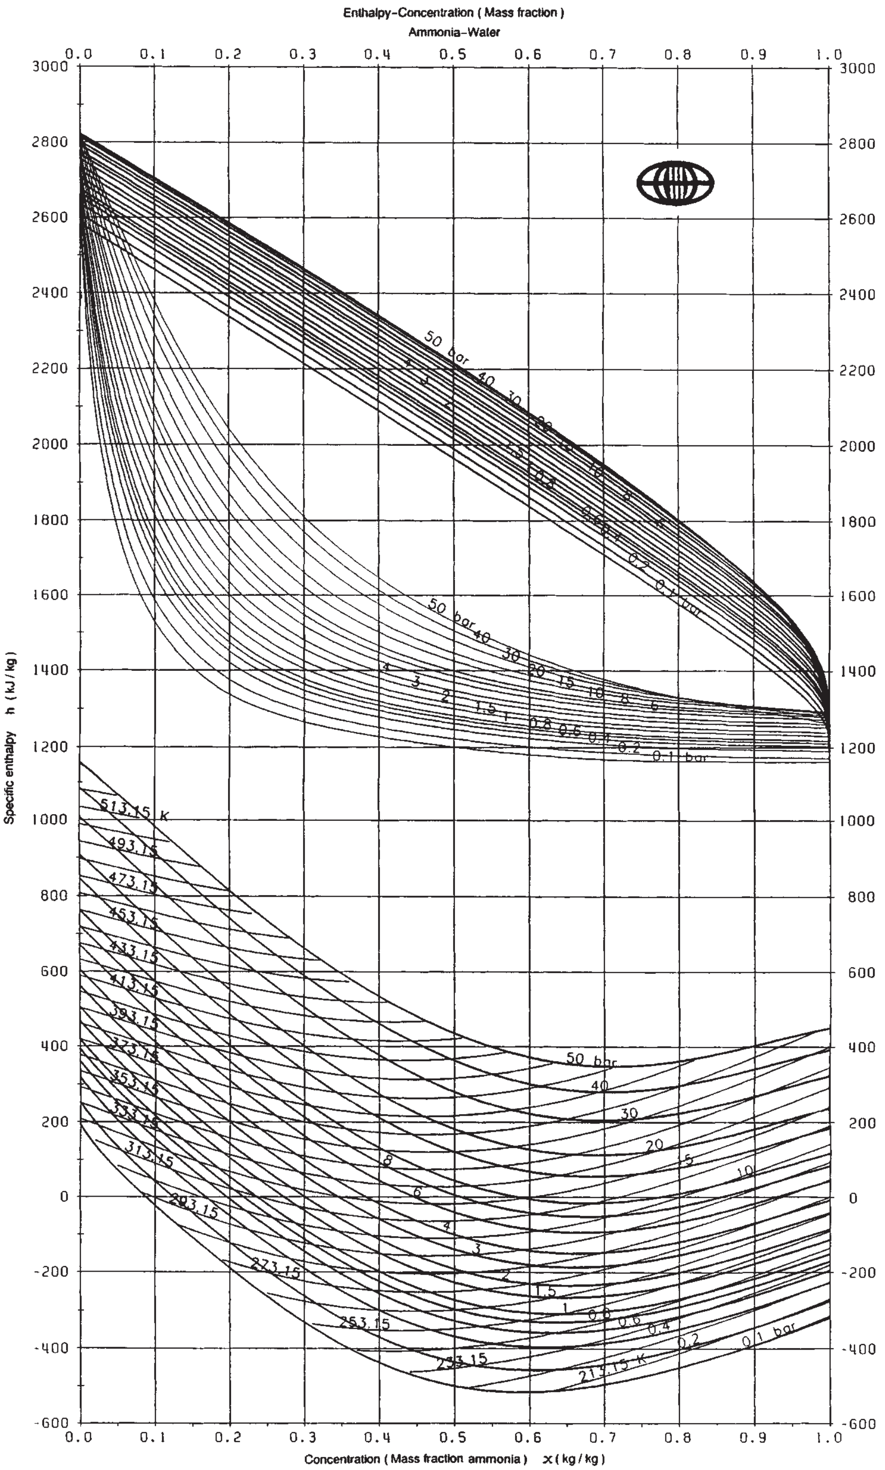

FIG. 2-7 Enthalpy-concentration diagram for aqueous ammonia. From *Thermodynamic and Physical Properties NH_3–H_2O*, Int. Inst. Refrigeration, Paris, France, 1994 (88 pp.). Reproduced by permission. In order to determine equilibrium compositions, draw a vertical from any liquid composition on any boiling line (the lowest plots) to intersect the appropriate auxiliary curve (the intermediate curves). A horizontal then drawn from this point to the appropriate dew line (the upper curves) will establish the vapor composition. The Int. Inst. Refrigeration publication also gives extensive *P-v-x* tables from −50 to 316°C. Other sources include Park, Y. M. and Sonntag, R. E., *ASHRAE Trans.*, **96,** 1 (1990): 150–159 (*x, h, s,* tables, 360 to 640 K); Ibrahim, O. M. and S. A. Klein, *ASHRAE Trans.*, **99,** 1 (1993): 1495–1502 (Eqs., 0.2 to 110 bar, 293 to 413 K); Smolen, T. M., D. B. Manley, et al., *J. Chem. Eng. Data,* **36** (1991): 202–208 (*p-x* correlation, 0.9 to 450 psia, 293–413 K); Ruiter, J. P., *Int. J. Refrig.,* **13** (1990): 223–236 gives ten subroutines for computer calculations.

*Values extracted and in some cases rounded off from those cited in Rabinovich (ed.), *Thermophysical Properties of Neon, Argon, Krypton and Xenon,* Standards Press, Moscow, 1976. This source contains values for the compressed state for pressures up to 1000 bar, etc. t = triple point. Above the solid line the condensed phase is solid; below it, it is liquid. The notation 5.646.–4 signifies 5.646×10^{-4}. At 83.8 K, the viscosity of the saturated liquid is 2.93×10^{-4} Pa·s = 0.000293 Ns/m². This book was published in English translation by Hemisphere, New York, 1988 (604 pp.).

*Values extracted and in some cases rounded off from those cited in Rabinovich (ed.), *Thermophysical Properties of Neon, Argon, Krypton and Xenon,* Standards Press, Moscow, 1976. v = specific volume, m³/kg; h = specific enthalpy, kJ/kg; s = specific entropy, kJ/(kg·K). This source contains an exhaustive tabulation of values. The notation 7.420.–4 signifies 7.420×10^{-4}. This book was published in English translation by Hemisphere, New York, 1988 (604 pp.). The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) has a thermodynamic chart for pressures from 1 to 2000 bar, temperatures from 90 to 700 K. Saturation and superheat tables and a chart to 50,000 psia, 1220 °R appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

Extensive tables for 10 properties from 0.9–100 bar, 86–400 K are given by Jacques, A., Fermi Accelerator Lab., Batavia, IL, rept TM 1517, 1988 (201 pp.). In Hilsenrath, J., C. G. Messina, et al., AEDC-TR-66-248 = AD 644 081, 1966 (121 pp.), thermodynamic properties and chemical composition from 2400 to 35,000 K are tabulated. See also Drellishak, K. S. et al., AEDC-TDR-63-146, 1963; AEDC-TDR-64-12 = AD 427839, 1964.

*Calculated values, from Wilson, Silverberg, and Zellner, USAF Aero Propulsion Laboratory. Rep. APL TDR 64-64 (AD 603 151), 1964. Relative volatility = $\alpha_{i-j} = (y_i/x_i)(x_j/y_j)$, where x = liquid composition, y = vapor composition. Pressure activity coefficient = $y_i P/x_i p^0$, where p^0 = vapor pressure. These data were confirmed by the analyses of Bender, *Cryogenics,* **13,** 11 (1973); and by Elshayal and Lu, *J. Chem. Eng. Data,* **16,** 31 (1971). See also Armstrong, G. T., J. M. Goldstein, et al., *J. Res. N.B.S.*, **55,** 5 (1955): 265–277; Bender, E., *Cryogenics,* **13,** 1 (1973): 11–18; Elshayal, I. M. and B. C-y Lu, *J. Chem. Eng. Data,* **16,** 1 (1971): 31–37; Funada, I., S. Yoshimura, et al., *Advan. Cryog. Engng.*, **7** (1982): 893–901; and Hwang, S-C., *Fluid Phase Equila.,* **37** (1987): 153–167.

*Converted from a tabulation by Counsell, Lawrenson, and Lees, Nat. Phys. Lab. Teddington (U.K.) Rep. Chem. 52, 1976. Another tabulation by Kesselman et al., in Vargaftik (ed.), *Tables on the Thermophysical Properties of Liquids and Gases*, Hemisphere, Washington and London, 1975, shows some differences. The notation 1.133.–6 signifies 1.133×10^{-6}. Other tables are given by Goodwin, R. D., *J. Phys. Chem. Ref. Data,* **17,** 4 (1988): 1541–1636.

*c = critical point. The notation 8.484.–4 signifies 8.484×10^{-4}.

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives material for integral degrees Celsius with temperatures on the LPTS 68 scale for saturation temperatures from −56.57 to 30.98 degrees Celsius. The thermodynamic diagram from 4 to 1000 bar extends to 420°C.

Saturation and superheat tables and a chart to 15,000 psia, 840°F appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see ASHRAE *Thermophysical Properties of Refrigerants,* 1993.

Saturation and superheat tables and a diagram to 200 bar, 1000 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.). Holste, J. C., D. M. Bailey, et al., *Energy Progr.*, **6,** 2 (1986): 125–130, give properties mainly in the range 0–100 bar, 200–450 K for the superheated vapor. Compare these with Angus, S., B. Armstrong, et al., *International Tables of the Fluid State—Carbon Dioxide,* Pergamon, Oxford, 1976 (377 pp.). In Miller, C. E. III and S. E. Wilder, NASA SP 3097, 1976 (489 pp.), many properties and decomposition products are tabulated for pressures from 10^{-7} to 10^4 atm., 100–25,000 K. For the range to 50 kb, 400–2100 K, see Bottinga, Y. and P. Richet, *Amer. J. Sci.,* **281** (1981): 615–660.

*P, v, h, and s values interpolated, extrapolated, and converted from Oguchi, *Reito,* **52** (1977): 869–889. c = critical point. The notation 5.370.–4 signifies 5.370×10^{-4}.

Equations and constants approximated to ASHRAE tables are given by Mecaryk, K. and M. Masaryk, *Heat Recovery Systems and CHP,* **11,** 2–3 (1991). The 1993 ASHRAE *Handbook—Fundamentals* (S.I. ed.) contains a saturation table from −140 to −45.65°C and an enthalpy–log-pressure diagram from 0.1 to 300 bar, −140 to 300°C. For properties to 1000 bar from 90 to 420 K, see Rublo, R. G., J. A. Zollweg, et al., *J. Chem. Eng. Data,* **36** (1991): 171–184. Saturation and superheat tables and a diagram to 80 bar, 600 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.*, Stanford Univ. publ., 1979 (173 pp.). Chari, Ph.D. thesis, University of Michigan, 1960, presents saturation-temperature tables in fps units for 1°F increments from −270 to −51°F. Thermodynamic and transport properties, equations, and computer code and tables at constant entropy from 89 to 845 K are given by Hunt, J. L. and Boney, L. R., NASA TN D-7181, 1973 (105 pp.), largely based upon the Chari data.

*Converted from tables in Vargaftik, *Tables of the Thermophysical Properties of Liquids and Gases,* Nauka, Moscow, 1972, and Hemisphere, Washington, 1975. m = melting point. The notation 2.66.–9 signifies 2.66×10^9.

Many of the Vargaftik values also appear in Ohse, R. W., *Handbook of Thermodynamic and Transport Properties of Alkali Metals,* Blackwell Sci. Pubs., Oxford, 1985 (1020 pp.). This source contains superheat data.

Saturation and superheat tables and a diagram to 30 bar, 1550 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.).

For a Mollier diagram from 0.1 to 327 psia, 1300–2700°R, see Weatherford, W. D., J. C. Tyler, et al., WADD-TR-61-96, 1961.

An extensive review of properties of the solid and the saturated liquid was given by Alcock, C. B., M. W. Chase, et al., *J. Phys. Chem. Ref. Data,* **23,** 3 (1994): 385–497.

*Converted and rounded off from the tables of Goodwin, Roder, and Straty, NBS Tech. Note 684, 1976. *v* = specific volume, m^3/kg; *h* = specific enthalpy, kJ/kg; *s* = specific entropy, kJ/(kg·K).

Saturation and superheat tables and a diagram to 300 bar, 580 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.). Saturation and superheat tables and a chart to 10,000 psia, 640°F appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993. The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) contains a thermodynamic diagram from 0.1 to 700 bar for temperatures to 600 K.

c = critical point.
Values interpolated and converted from *Heat Exchanger Design Handbook*, vol. 5, Hemisphere, Washington, DC, 1983, and from various literature sources.

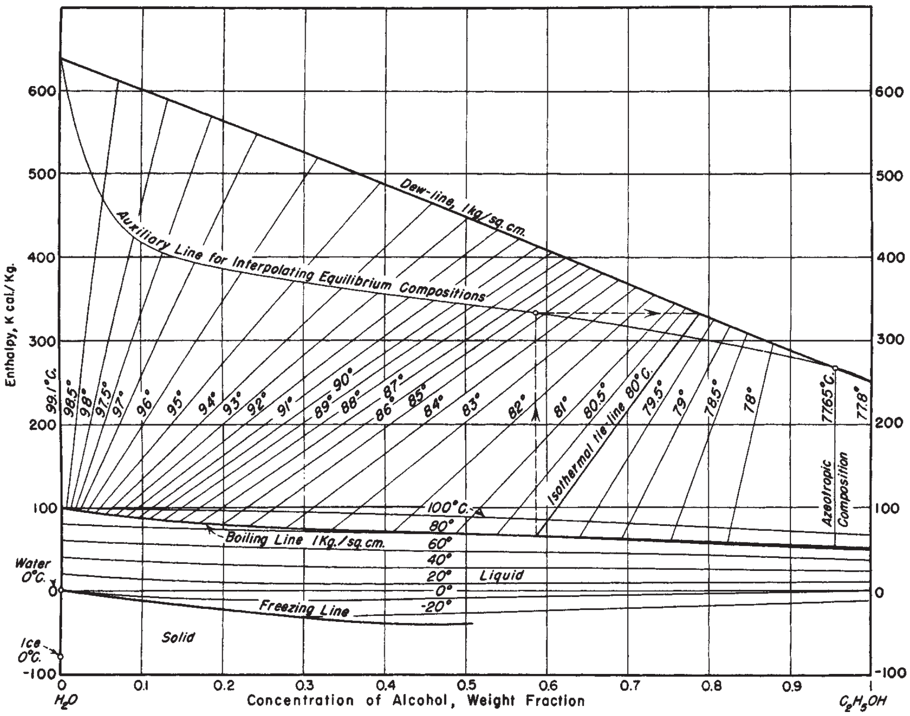

FIG. 2-10 Enthalpy-concentration diagram for aqueous ethyl alcohol. Reference states: Enthalpies of liquid water and ethyl alcohol at 0°C are zero. NOTE: In order to interpolate equilibrium compositions, a vertical may be erected from any liquid composition on the boiling line and its intersection with the auxiliary line determined. A horizontal from this intersection will establish the equilibrium vapor composition on the dew line. (*Bosnjakovic,* Technische Thermodynamik, *T. Steinkopff, Leipzig, 1935.*)

t = triple point; c = critical point. $h_f = s_f = 0$ at 233.15 K = −40°C.

Converted from Jacobsen, R. T., M. Jahangiri, et al., *Ethylene—Intl. Thermodyn. Tables of the Fluid State—10,* Blackwell Sci. Publ., Oxford, U.K., 1988 (299 pp.).

Saturation and superheat tables and a diagram to 100 bar, 460 K are given by Reynolds, W. C., *Thermodynamic properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.). Saturation and superheat tables and a chart to 6000 psia, 360°F appear in *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) has a thermodynamic chart for pressures from 0.1 to 400 bar and temperatures up to 460 K.

*Extracted from Prydz and Straty, NBS Tech. Note 392, 1970. This source is recommended for other pressures and temperatures. Other information is contained in *J. Chem. Phys.*, **53** (1970): 2359; and *J. Res. NBS*, **74A** (1970): 499, 661, 747.

TABLE 2-261 Flutec

Proprietary name for a series of fluorocarbons produced by the Imperial Smelting Corp., Avonmouth, Bristol, UK. Bulletins of thermodynamic properties include PP1 (C_6F_{14}), PP2 (C_7F_{14}), PP3 (C_8F_{16}), PP5 ($C_{10}F_{18}$), PP9 ($C_{11}F_{20}$), and PP50, usually for 0.1–100 kg/m^2, 0–500°C. See also Green, S. W., *Chem. & Ind.* (1969): 63–67.

TABLE 2-262 Halon

A series of fire-extinguishing fluids. Halon 1211 is produced by ICI, and Halon 1301, by duPont, the latter issuing a bulletin with thermodynamic properties and a diagram for the range 0.6–600 psia, –160–460°F.

*Extracted from Tsederberg, Popov, et al., *Thermodynamic and Thermophysical Properties of Helium,* Atomizdat, Moscow, 1969, and NBS-NSF TT 50096, 1971. Copyright material. Reproduced by permission. This source contains entries for many more temperatures and pressures than can be reproduced here. v = volume, m^3/kg; h = enthalpy, kJ/kg; s = entropy, kJ/(kg·K).

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) has a thermodynamic chart for pressures from 0.1 to 50 bar and temperatures from 2.5 to 15 K. Saturation and superheat tables to 9000 psia, 800°R; and a chart to 700 psia, 40°R appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993. A useful compilation of properties is given by Betts, D. S., *Cryogenics,* **16,** 1 (1976): 3–16. A 32-term equation of state for the range up to 20,000 bar, 2–1500 K is given by McCarty, R. D. and V. D. Arp, *Advan. Cryog. Engng.,* **35** (1990): 1465–1475.

*Values extracted and sometimes rounded off from the tables of McCarty, Hord, and Roder, NBS Monogr. 168, 1981. This source contains an exhaustive tabulation of property values for both the normal and the para forms of hydrogen. v = specific volume, m^3/kg; h = specific enthalpy, kJ/kg; s = specific entropy, kJ/(kg·K).

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) has a thermodynamic diagram for 0.1 to 500 bar for temperatures up to 100 K. Tables and a Mollier chart from 10^{-4} to 1000 atm, 300–20,000 K are given by Kubin, R. F. and L. L. Presley, NASA SP 3002, 1964. Liebenberg, D. H., R. L. Mills, and others, in LA-6645-MS, 1977 (26 pp.), give properties from 75 to 307 K for pressures from 2 to 20 kbar. See also Baker, J. R. and H. F. Swift, *J. Appl. Phys.*, **43,** 3 (1972): 950–953. An extensive collection of data for H_2, D_2, T_2, and so on below 30 K is given by Souers, P. C., UCRL 52628, 1979 (91 pp.); and for temperatures below 40 K by Roder, H. M., G. E. Childs, et al., NBS TN 641, 1973 (114 pp.).

Saturation and superheat tables to 10,000 psia, 900°R and a chart to 180°R appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For viscosity, thermal conductivity, and specific heat, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

*Values extracted and occasionally rounded off from McCarty, Hord, and Roder, NBS *Monogr.* 168, 1981. t = triple point; c = critical point.

Saturation and superheat tables to 12,000 psia, 900°R and a chart to 180°R appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants*, ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants*, ASHRAE, 1993. The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) has a thermodynamic chart for pressures from 0.1 to 1000 bar for temperatures up to 100 K.

*Values reproduced or converted from a tabulation by Tsykalo and Tabachnikov in V. A. Rabinovich (ed.), *Thermophysical Properties of Gases and Liquids,* Standartov, Moscow, 1968; NBS-NSF transl. TT 69-55091, 1970. The reader may be reminded that very pure hydrogen peroxide is very difficult to obtain owing to its decomposition or instability. c = critical point. The FMC Corp., Philadelphia, PA tech. bull. 67, 1969 (100 pp.) contains an enthalpy-pressure diagram to 3000 psia, 1100 K.

TABLE 2-274 Hydrogen Sulfide

West, J. R., *Chem. Eng. Progr.*, **44,** 4 (1948): 207–292 gives tables and a chart for the range 1–90 atm., −76 to 1300°F while properties from 10 to 330 bar, 300 to 500 K were tabulated by Lui, C-H., D. M. Bailey, et al., *Hydroc. Proc.*, **65,** 7 (July 1986): 41–43.

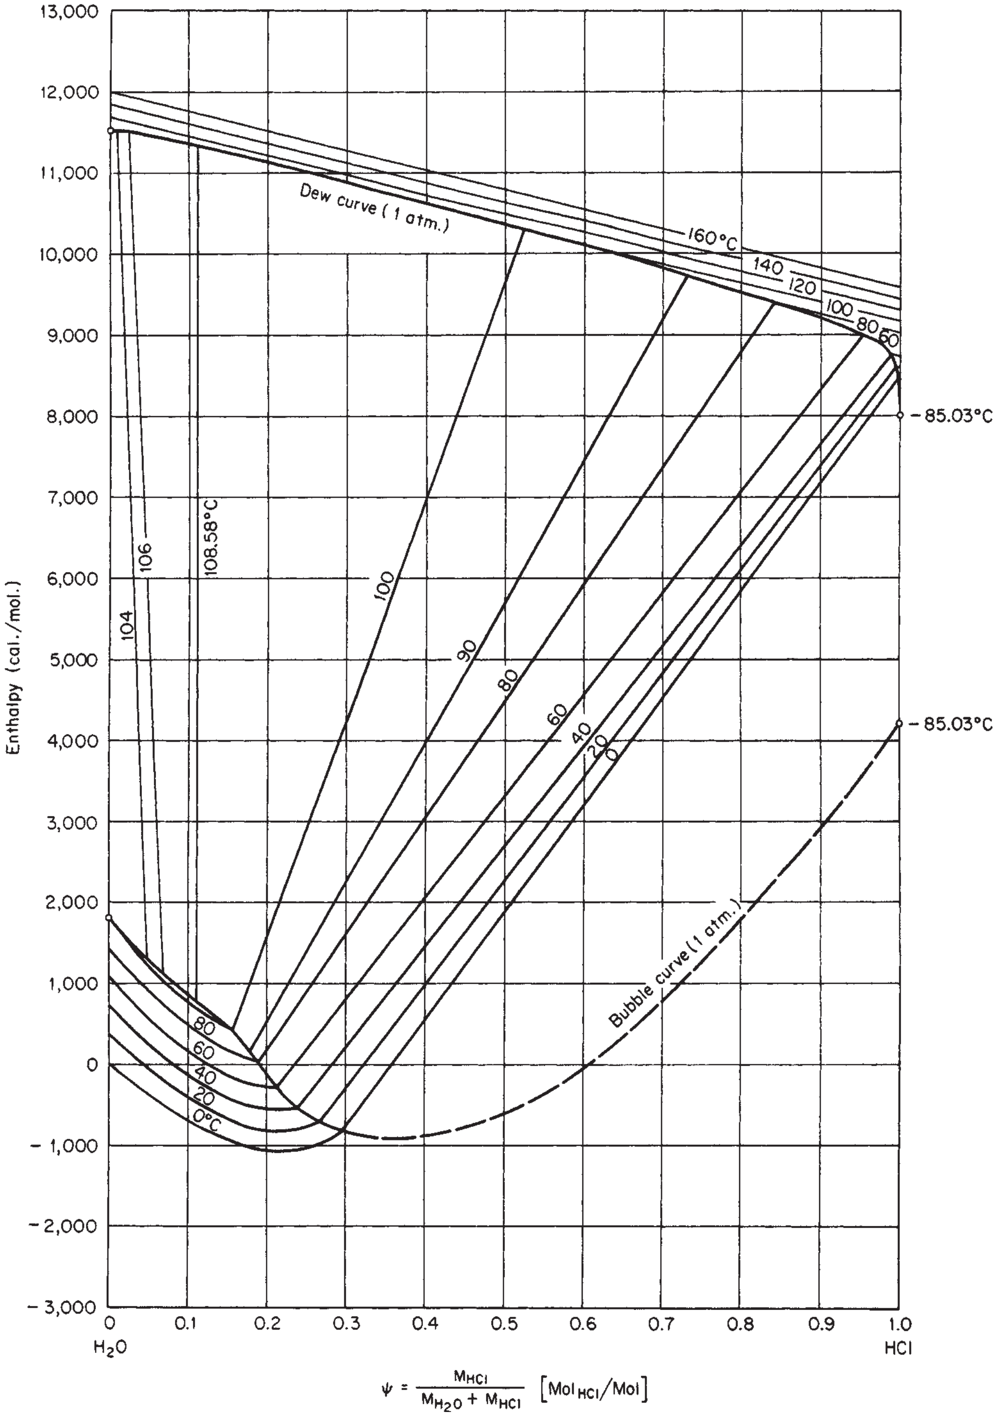

FIG. 2-11 Enthalpy-concentration diagram for aqueous hydrogen chloride at 1 atm. Reference states: enthalpy of liquid water at 0°C is zero; enthalpy of pure saturated HCl vapor at 1 atm (−85.03°C) is 8000 kcal/mol. NOTE: It should be observed that the weight basis includes the vapor, which is particularly important in the two-phase region. Saturation values may be read at the ends of the tie lines. [*Van Nuys,* Trans. Am. Inst. Chem. Eng., ***39,*** *663 (1943).*]

*Values reproduced or converted from Goodwin, NBSIR 79-1612, 1979. t = triple point; c = critical point. The notation 1.9.–7 signifies 1.9×10^{-7}.

Slightly different values for the range 0.5 to 34.5 bar, 250–404 K appear in Waxman, M. and J. S. Gallagher, *J. Chem. Eng. Data,* **28,** (1983): 224–241. This source also contains superheat tables for 1–400 bar, 250–600 K.

Saturation and superheat tables and a diagram to 200 bar, 600 K are given by Reynolds, W. C., *Thermodynamic properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.). Saturation and superheat tables and a chart to 10,000 psia, 640°F appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993. Equations and data for thermal conductivity and viscosity are given by Nieuwoldt, J. C., B. LeNeindre, et al., *J. Chem. Eng. Data,* **32,** (1987): 1–8.

*Values extracted and in some cases rounded off from those cited in Rabinovich (ed.), *Thermophysical Properties of Neon, Argon, Krypton and Xenon,* Standards Press, Moscow, 1976. This source contains an exhaustive tabulation of values. v = specific volume, m^3/kg; h = specific enthalpy, kJ/kg; s = specific entropy, kJ/(kg·K). The notation 3.49.–4 signifies 3.49×10^{-4}. This book was published in English translation by Hemisphere, New York, 1988 (604 pp.).

*Converted from tables in Vargaftik, *Tables of the Thermophysical Properties of Liquids and Gases,* Nauka, Moscow, 1972, and Hemisphere, Washington, 1975. m = melting point. The notation 1.78.–13 signifies 1.78×10^{-13}.

Many of the Vargaftik values also appear in Ohse, R. W., *Handbook of Thermodynamic and Transport Properties of Alkali Metals,* Blackwell Sci. Pubs., Oxford, 1985 (1020 pp.). This source contains superheat data.

Saturation and superheat tables and a diagram to 14 bar, 2200 K are given by Reynolds, W. C., *Thermodynamic properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.). For a Mollier diagram from 0.1 to 140 psia, 2100–3600°R, see Weatherford, P. M., J. C. Tyler, et al., WADD-TR-61-96, 1961.

An extensive review of properties of the solid and the saturated liquid was given by Alcock, C. B., M. W. Chase, et al., *J. Phys. Chem. Ref. Data,* **23,** 3 (1994): 385–497.

TABLE 2-279 Lithium Bromide—Water Solutions

Ruiter, J. P., *Rev. Int. Froid = Int. J. Refrig.,* **13** (1990): 223–236 gives subroutines for computer calculations. See also ASHRAE *Handbook—Fundamentals.*

*From Vukalovich, Ivanov, Fokin, and Yakovlev, *Thermophysical Properties of Mercury,* Standartov, Moscow, 1971. For the saturated liquid the specific volume at 203.15 K is 7.26239×10^{-5} m³/kg, etc. All the tabular values for 203.15 K, 213.15 K, 223.15 K, and 233.15 K represent a metastable equilibrium between the subcooled liquid and the saturated vapor.

Saturation and superheat tables and a diagram to 100 bar, 1600 K are given by Reynolds, W. C., *Thermodynamic properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.). For a Mollier diagram from 1 to 8200 psia and 2700°R, see Weatherford, W. D., J. C. Tyler, et al., WADD-TR-61-96, 1961.

Converted and interpolated from Goodwin, R. D., *J. Phys. Chem. Ref. Data,* **16,** 4 (1987): 799–891. These extensive tables extend to 700 bar for temperatures from 175.6 to 800 K. Another extensive compilation is by deReuck, K. M. and R. J. B. Craven, *Methanol,* C.R.C. Press, 1993 (320 pp.).

Equations and diagrams to 30 bar, 200°C are given by Eicholz, H. D., S. Schulz, et al., *Kalte u Klim.,* no. 9, (1981) 322–331. For pressures to 1040 bar, 298–489 K, see Machado, J. R. S. and W. B. Street, *J.Chem.Eng.Data,* **28** (1983): 218–223; to 2800 bar from 273 to 333 K, see Sun, T., S. N. Biswas, et al., *J. Chem. Eng. Data,* **33** (1988): 395–398. Dissociation was considered by Yerlett, T. K. and C. J. Wormald, *J. Chem. Thermo.,* **18** (1986): 719–726, and by Kazarnovskii, Ya. S. and E. V. Pavlova, *Russ. J. Phys. Chem.,* **56,** 6 (1982): 847–851.

*Values extracted and in some cases rounded off from those cited in Rabinovich (ed.), *Thermophysical Properties of Neon, Argon, Krypton and Xenon,* Standards Press, Moscow, 1976. m = melting point; c = critical point. The notation 6.654.–4 signifies 6.654×10^{-4}. This source contains values for the compressed state up to 1000 bar, etc. This book was published in English translation by Hemisphere, New York 1988 (604 pp.).

Saturation and superheat tables and a diagram to 200 bar, 320 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.). Saturation and superheat tables to 60,000 psia, 900°R and a chart to 4000 psia, 560°R appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

*Values extracted and in some cases rounded off from those cited in Rabinovich (ed.), *Thermophysical Properties of Neon, Argon, Krypton and Xenon,* Standards Press, Moscow, 1976. This source contains an exhaustive tabulation of values. v = specific volume, m^3/kg; h = specific enthalpy, kJ/kg; s = specific entropy, kJ/(kg·K). The notation 6.76.–3 signifies 6.76×10^{-3}. This book was published in English translation by Hemisphere, New York, 1988 (604 pp.).

*Reproduced and converted from Vasserman and Rabinovich, *Thermophysical Properties of Liquid Air and Its Components,* Standartov, Moscow, 1968; and Israel Program for Scientific Translations, TT 69-55092, 1970. t = triple point; c = critical point.

Other extensive tables are given by Angus, S., *International Thermodynamic Tables of the Fluid State—6. Nitrogen,* Pergamon, 1977 (244 pp.); Hanley, H. J. M., R. D. McCarty, et al., *J. Phys. Chem. Ref. Data,* **3** (1974): 979–1019.

Saturation and superheat tables to 30,000 psia and a chart to 10,000 psia, all to 860°R, appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) has a thermodynamic chart for pressures from 0.1 to 800 bar and temperatures from 80 to 500 K.

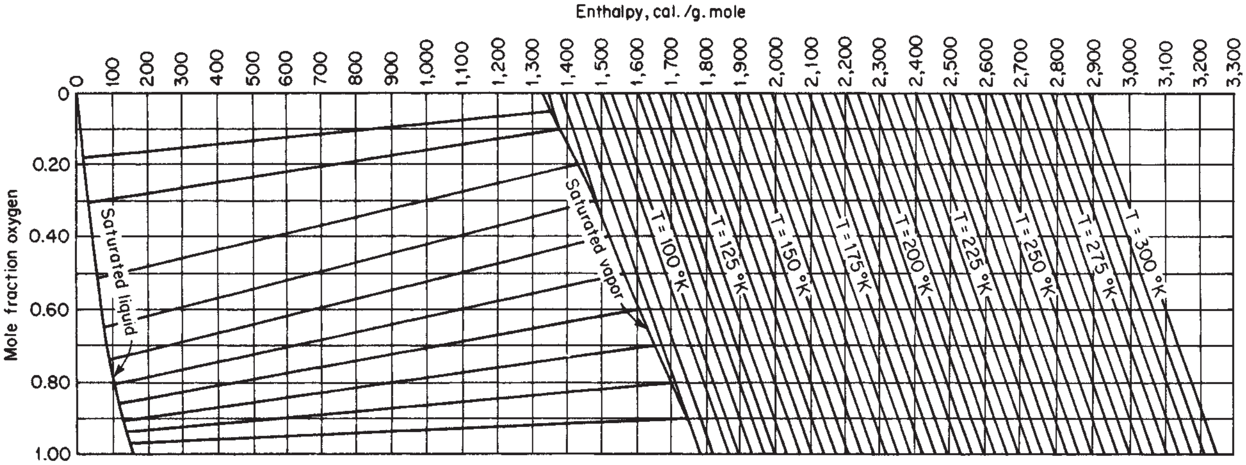

FIG. 2-16 Enthalpy-concentration diagram for oxygen-nitrogen mixture at 1 atm. Reference states: Enthalpies of liquid oxygen and liquid nitrogen at the normal boiling point of nitrogen are zero. (*Dodge,* Chemical Engineering Thermodynamics, *McGraw-Hill, New York, 1944.*) Wilson, Silverberg, and Zellner, AFAPL TDR 64-64 (AD 603151), 1964, p. 314, present extensive vapor-liquid equilibrium data for the three-component system argon-nitrogen-oxygen as well as for binary systems including oxygen-nitrogen.

TABLE 2-295 Pentane

Canjar and Manning (*Thermodynamic Properties and Reduced Correlations for Gases,* Gulf, Houston, 1967) give extensive tables and an enthalpy–log-pressure diagram, based upon Brydon, Walen, and Canjar [*Chem. Eng. Prog. Symp. Ser.,* **49,** 7, (1951): 151–157]. For isopentane, Arnold, Liou, and Eldridge [*J. Chem. Eng. Data,* **10,** 88 (1965)] used the Benedict-Webb-Rubin equation to generate information to 600°F and 60 atm. Das and Kuloor used the same equation in *Ind. J. Technol.,* **5,** 46 (1967) to calculate information up to 1500 K and 1000 atm. Saturation and superheat tables and a diagram to 200 bar, 600 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.). For equations, see Grigoryev, B. A., Yu. L. Rastorguyev, et al., *Int. J. Thermophys.,* **11,** 3 (1990): 487–502.

*Converted from tables in Vargaftik, *Tables of the Thermophysical Properties of Liquids and Gases,* Nauka, Moscow, 1972; and Hemisphere, Washington, 1975. m = melting point. The notation 1.37.–9 signifies 1.37×10^{-9}.

Many of the Vargaftik values also appear in Ohse, R. W., *Handbook of Thermodynamic and Transport Properties of Alkali Metals,* Blackwell Sci. Pubs., Oxford, 1985 (1020 pp.). This source contains superheat data. Saturation and superheat tables and a diagram to 30 bar, 1650 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.). For a Mollier diagram from 0.1 to 250 psia, 1300 to 2700°R, see Weatherford, W. D., J. C. Tyler, et al., WADD-TR-61-96, 1961. An extensive review of properties of the solid and the saturated liquid is given by Alcock, C. B., M. W. Chase, et al., *J. Phys. Chem. Ref. Data,* **23,** 3 (1994): 385–497.

*Values converted and mostly rounded off from those of Goodwin, NBSIR 77-860, 1977. t = triple point; c = critical point. The notation 3.0.–9 signifies 3.0×10^{-9}. Later tables for the same temperature range for saturation and for the superheat state from 0.1 to 1000 bar, 85.5 to 600 K, were published by Younglove, B. A. and J. F. Ely, *J. Phys. Chem. Ref. Data,* **16,** 4 (1987): 685–721, but the lower temperature saturation tables contain some errors.

Saturation and superheat tables and a chart to 10,000 psia, 800°F appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.).

For thermodynamic properties for 0.1 to 1000 bar, 100 to 700 K, see Sychev, V. V., A. A. Vasserman, et al., *Thermodynamic Properties of Propane,* Hemisphere, New York, NY, 1991 (275 pp.).

Saturation and superheat tables and a diagram to 200 bar, 600 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.).

For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

Converted and interpolated from Angus, S., B. Armstrong, et al., *International Thermodynamic Tables of the Fluid State—7. Propylene,* Pergamon, Oxford, 1980 (401 pp.).

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) has a thermodynamic chart for pressures from 0.1 to 1000 bar for temperatures up to 580 K. Saturation and superheat tables and a diagram to 30,000 psia, 580°F appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

*P, v, h, and s data interpolated from Perelshteyn (ed.), *Tables and Diagrams of the Thermodynamic Properties of Refrigerants 12, 13 and 22,* Moscow, 1971. c_p, μ, and k data interpolated and converted from *Thermophysical Properties of Refrigerants,* American Society of Heating, Refrigerating and Air-Conditioning Engineers, New York, 1976. c = critical point. The notation 6.209.–4 signifies 6.209×10^{-4}. The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives a saturation table from –150 to 96.14°C and an enthalpy–log-pressure diagram from 0.1 to 150 bar, –60 to 200°C. For experimental isochores for the compressed liquid from 12 to 297 bar, 120 to 378 K, see Blanke, W. and R. Weiss, *PTB Bericht W 30,* Braunschweig, Germany, 1992 (54 pp.). Equations and constants approximated to 1985 ASHRAE tables are given by Mecarik, K. and M. Masaryk, *Heat Recovery Systems and CHP,* **11** 2/3 (1991): 193–197. Saturation and superheat tables and a diagram to 100 bar, 620 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (179 pp.). For tables and a chart to 2000 psia, 480°F, see Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

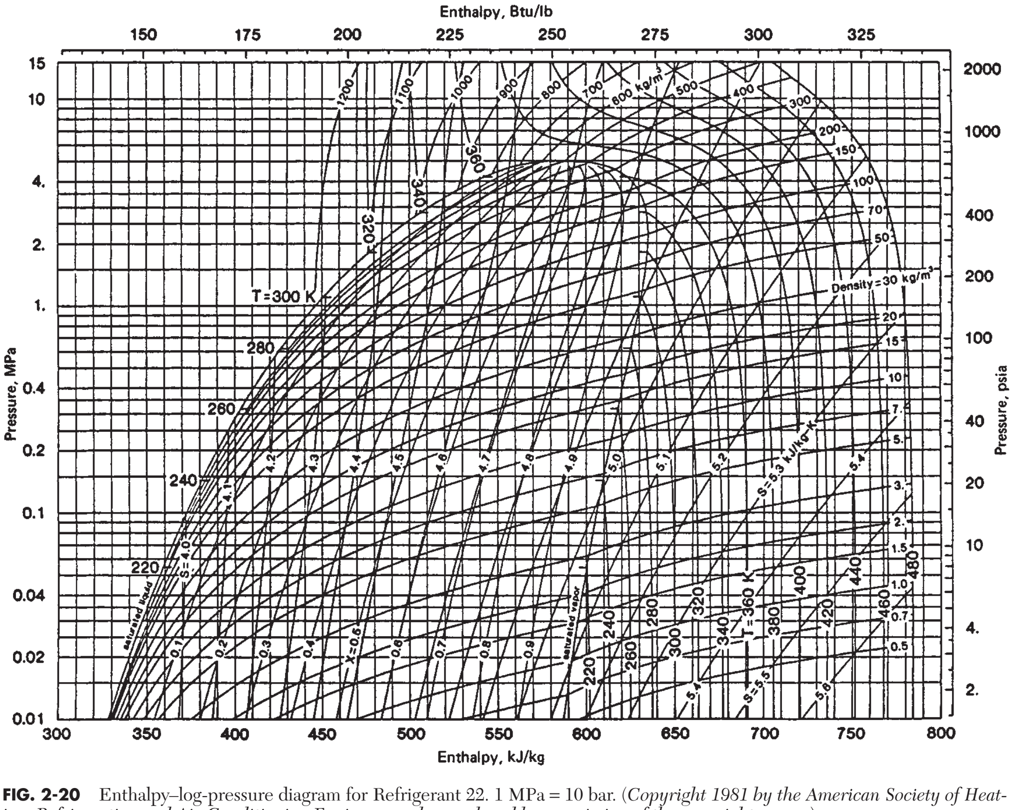

FIG. 2-20 Enthalpy–log-pressure diagram for Refrigerant 22. 1 MPa = 10 bar. (*Copyright 1981 by the American Society of Heating, Refrigerating and Air-Conditioning Engineers and reproduced by permission of the copyright owner.*)

b = normal boiling point; c = critical point. $h_f = s_f = 0$ at 233.15 K = −40°C. Interpolated and converted from ASHRAE *Handbook—Fundamentals,* 1993. Experimental P–ρ–T data from 95 to 413 K reported in *J. Phys. Chem.,* **89** (1985): 4637–4646 were used by Rubio, R. G., J. A. Zollweg, et al., *J. Chem. Eng. Data,* **36,** (1991): 171–184, to calculate properties up to 1000 bar from 126 to 332° K.

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives a saturation table from −100 to 25.92°C and an enthalpy–log-pressure diagram from 0.1 to 80 bar, −100 to 280°C. Equations and constants approximated to the 1985 ASHRAE tables are given by Mecaryk, K. and M. Masaryk, *Heat Recovery Systems and CHP,* **11,** 2/3 (1991): 193–197.

For an enthalpy–log-pressure diagram from 0.005 to 200 bar, −140 to 180°C, see Morsy, T. E., *Kaltetechnik—Klimat.,* **18,** 9 (1966): 347–349. Saturation and superheat tables and a diagram to 100 bar, 600 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.).

For tables and a chart to 1000 psia, 560°F, see Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (21 pp.).

For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

c = critical point. The notation 7.845.–4 signifies 7.845×10^{-4}. *P, v, T, h, s,* and c_p converted and extrapolated from Defibaugh, D. R., G. Morrison, et al., *J. Chem. Eng. Data,* **39** (1994): 333–340. Saturated liquid and vapor viscosities from smooth curve fits of Oliveira, C. M. B. P. and W. A. Wakeham, *Int. J. Thermophys.,* **14,** 6 (1993): 1131–1143. Thermal conductivity values based upon papers by Geller, V. Z. and M. E. Perlaitis, and by Gross, *Proc. 10th Symp. Thermophys. Props.,* Boulder, CO, 1994.

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives a saturation table to 78.41°C and a diagram to 200 bar, 200°C.

*Values reproduced or converted from Table 8, p. 17.91, *ASHRAE Handbook, 1981: Fundamentals,* American Society of Heating, Refrigerating and Air-Conditioning Engineers, Atlanta, 1981. Copyright material. Reproduced by permission of the copyright owner. c = critical point. The notation 5.908.–4 signifies 5.908×10^{-4}. The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives a saturation table from −30 to 214.4°C and an enthalpy–log-pressure diagram from 0.1 to 60 bar, 0 to 260°C. Equations and constants approximated to the 1985 ASHRAE tables were given by Mecaryk, K. and M. Masaryk, *Heat Recovery Systems and CHP,* **11,** 2/3 (1991): 193–197. For experimental isochores for the compressed liquid from 21 to 304 bar, 266 to 453 K, see Blanke, W. and R. Weiss, PTB Bericht W 30, Braunschweig, Germany, 1992 (54 pp.).

For tables to 300 bar, 460 K, see Geller, V. Z. and V. A. Rabinovich (ed.), *Thermophysical Properties of Substances and Materials,* Standartov, Moscow, **7** (1973): 135–154. Mastroianni, M. J., R. F. Stahl, et al., *J. Chem. Eng. Data,* **23,** 2 (1978): 113–118 give a diagram to 1000 psia, 600°F. Tables and a diagram to 800 psia, 520°F are given by Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

*Values reproduced or converted from Table 9, p. 17.93, *ASHRAE Handbook, 1981: Fundamentals,* American Society of Heating, Refrigerating and Air-Conditioning Engineers, Atlanta, 1981. Copyright material. Reproduced by permission of the copyright owner. c = critical point. The notation 6.326.–4 signifies 6.326×10^{-4}. The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives a saturation table from –80 to 145.88°C and an enthalpy–log-pressure diagram from 0.1 to 100 bar, –20 to 220°C. Equations and constants approximated to the 1985 ASHRAE tables were given by Mecaryk, K. and M. Masaryk, *Heat Recovery Systems and CHP.,* **11,** 2/3 (1991): 193–197.

Saturation and superheat tables and a diagram to 60 bar, 540 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (179 pp.). Tables and a chart to 1500 psia, 480°F are given by Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

* = triple point; † = normal boiling point; ‡ = critical point. Converted, extrapolated and interpolated from 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) $h_f = s_f = 0$ at 233.15 K = −40°C. This source also contains an enthalpy–log-pressure diagram from 0.3 to 100 bar, −65 to 175°C. An apparently identical diagram but a different saturation table is contained in Duarte-Garza, H.A., Hwang, C.A. et al., ASHRAE Trans., **99,** 2 (1993): 649–664. R124: The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) contains a saturation table from −60 to 122.47°C.

t = triple point, *c* = critical point. $h_f = s_f = 0$ at −40°C = 233.15 K. *T, v, h,* and *s* interpolated and converted from *Refrigerant 134a—Thermodynamic and Physical Properties,* Int. Inst. Refrig., Paris, France, 1992 (28 pp.).

Other properties from this source and from Oliveira, C. M. B. P. and W. A. Wakeham, *Int. J. Thermophys.,* **14,** 1 (1993): 33–44; Krauss, R., J. Luettmer-Strathmann, et al., *Int. J. Thermophys.,* **14,** 4 (1993): 951–988; ASHRAE *Handbook—Fundamentals,* Atlanta, GA, 1993; ICI KLEA 134a bulletin, 1993 (43 pp.); and *R134a—Thermodynamic and Physical Properties,* Int. Inst. Refrig., Paris, France, 1992 (28 pp.).

Papers giving polynomial curve fits and similar simple equations include Cleland, A. C., *Rev. Int. Froid = Int. J. Refrig.,* **17,** 4 (1994): 245–249; Dobrokhotov, A., A. Grebenkov, et al., *Proc. 14th Japan Symp. Thermophys. Props.,* (1993): 271–274; Huber, M. L. and J. F. Ely, *Rev. Int. Froid = Int. J. Refrig.,* **17,** 1 (1994): 18–31 (includes extensive list of vapor pressure and liquid density sources for many refrigerants); Modic, J., *Proc. 11th Int. Symp. Htg, Refrig and Air-Condg.,* Zagreb, (1991): 174–185; and Kabelac, S., *Int. J. Refrig.,* **14,** (1991): 217–222. The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives saturation data for integral degrees Celsius with temperatures on the ITS 90 scale from −103.03°C to 101.03°C. The thermodynamic diagram from 0.1 to 200 bar extends to 320°C.

*Values reproduced and converted from Table 10, p. 17.95, *ASHRAE Handbook, 1981: Fundamentals,* American Society of Heating, Refrigerating and Air-Conditioning Engineers, Atlanta, 1981. Copyright material. Reproduced by permission of the copyright owner. c = critical point. The notation 7.505.–4 signifies 7.505×10^{-4}.

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives material for integral degrees Celsius with temperatures on the IPTS 68 scale from –50 to 125°C. The thermodynamic diagram from 0.1 to 35 bar extends to 180°C. For experimental isochores for the compressed liquid from 6 to 298 bar, 147 to 432 K, see Blanke, W. and R. Weiss, *PTB Bericht W 30,* Braunschweig, Germany, 1992 (54 pp.). Tables and a diagram to 500 psia, 400°F are given in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat, thermal conductivity, and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

*From published data, Chemicals Division, Union Carbide Corporation. Used by permission. The paper describing these data is by Shank, *ASHRAE J.,* **7** (1965): 94–101. *c* = critical temperature.

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives material for integral degrees Celsius with temperatures on the ITS 90 scale from −118.59 to 113.26°C. The thermodynamic diagram from 0.1 to 30 bar extends to 180°C. For tables and a diagram to 400 psia, 360°F, see Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat and viscosity, see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993. Thermal conductivity data as a function of pressure and temperature are reported by Krauss, R. and K. Stephan, *Proc. 12th Symp. Thermophys. Props.,* Boulder, CO, 1994.

*Values reproduced and converted from Table 12, p. 17.99, *ASHRAE Handbook, 1981: Fundamentals,* American Society of Heating, Refrigerating and Air-Conditioning Engineers, Atlanta, 1981. Copyright material. Reproduced by permission of the copyright owner. c = critical point. The notation 6.966.–4 signifies 6.966×10^{-4}.

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives material for integral degrees Celsius with temperatures on the IPTS 68 scale from −70 to 105.60°C. The thermodynamic diagram from 0.1 to 70 bar extends to 240°C. Equations and constants approximated to the 1985 ASHRAE tables were given by Mecaryk, K. and M. Masaryk, *Heat Recovery Systems and CHP,* **11,** 2/3 (1991): 193–197. Saturation and superheat tables and a diagram to 80 bar, 560 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.). Tables and a chart to 1000 psia, 480°F are given by Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). Specific heat and viscosity appear in *Thermophysical Properties of Refrigerants,* ASHRAE, 1993.

**P, v, h,* and *s* values reproduced and converted from Table 14, p. 17.103, *ASHRAE Handbook, 1981: Fundamentals,* American Society of Heating, Refrigerating and Air-Conditioning Engineers, Atlanta, 1981. Copyright material. Reproduced by permission of the copyright owner. c_p, μ, and k values interpolated and converted from *Thermophysical Properties of Refrigerants,* American Society of Heating, Refrigerating and Air-Conditioning Engineers, New York, 1976. c = critical point. The notation 6.384.–4 signifies 6.384×10^{-4}.

Saturation and superheat tables and a diagram to 80 bar, 600 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.). Tables and a chart to 1000 psia, 460°F are given by Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants,* ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat and viscosity see *Thermophysical Properties of Refrigerants,* ASHRAE, 1993. The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives material for integral degrees Celsius with temperatures on the IPTS 68 scale for saturation conditions from –125 to 19.50°C. The thermodynamic diagram from 0.1 to 80 bar extends to 220°C.

*Converted from tables in Vargaftik, *Tables of the Thermophysical Properties of Liquids and Gases,* Nauka, Moscow, 1972, and Hemisphere, Washington, 1975. m = melting point. The notation 2.46.–9 signifies 2.46×10^{-9}.

Many of the Vargaftik values also appear in Ohse, R. W., *Handbook of Thermodynamic and Transport Properties of Alkali Metals,* Blackwell Sci. Pubs., Oxford, 1985 (1020 pp.). This source contains superheat data.

Saturation and superheat tables and a diagram to 40 bar, 1600 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.,* Stanford Univ. publ., 1979 (173 pp.).

For a Mollier diagram from 0.1 to 320 psia, 1200 to 2700°R, see Weatherford, W. D., J. C. Tyler, et al., WADD-TR-61-96, 1961. An extensive review of properties of the solid and the saturated liquid was given by Alcock, C. B., M. W. Chase, et al., *J. Phys. Chem. Ref. Data,* **23,** 3 (1994): 385–497.

c = critical point.

s_f values converted from Cordfunke, E. H. P. and R. J. M. Konings, *Thermochemical Data for Reactor Materials and Fission Products*, North Holland Elsevier, NY, 1990. s_g determined as $s_f + (h_g - h_f)/T$. μ_g and k_g values estimated by P. E. Liley. All other values are from Fink, J. K. and L. Leibowitz, Argonne Nat. Lab Rept. ANL/RE-95-2, 1995. The Fink and Leibowitz work also appeared in *High Temp. Materials Sci.*, **35,** 65–103, 1996. Saturation and superheat tables and a diagram to 14 bar, 1700 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.*, Stanford Univ. publ., 1979 (173 pp.). For a Mollier diagram for 0.1–150 psia, 1500–2700°R, see Weatherford, P. M., J. C. Tyler, et al., WADD-TR-61-96, 1961.

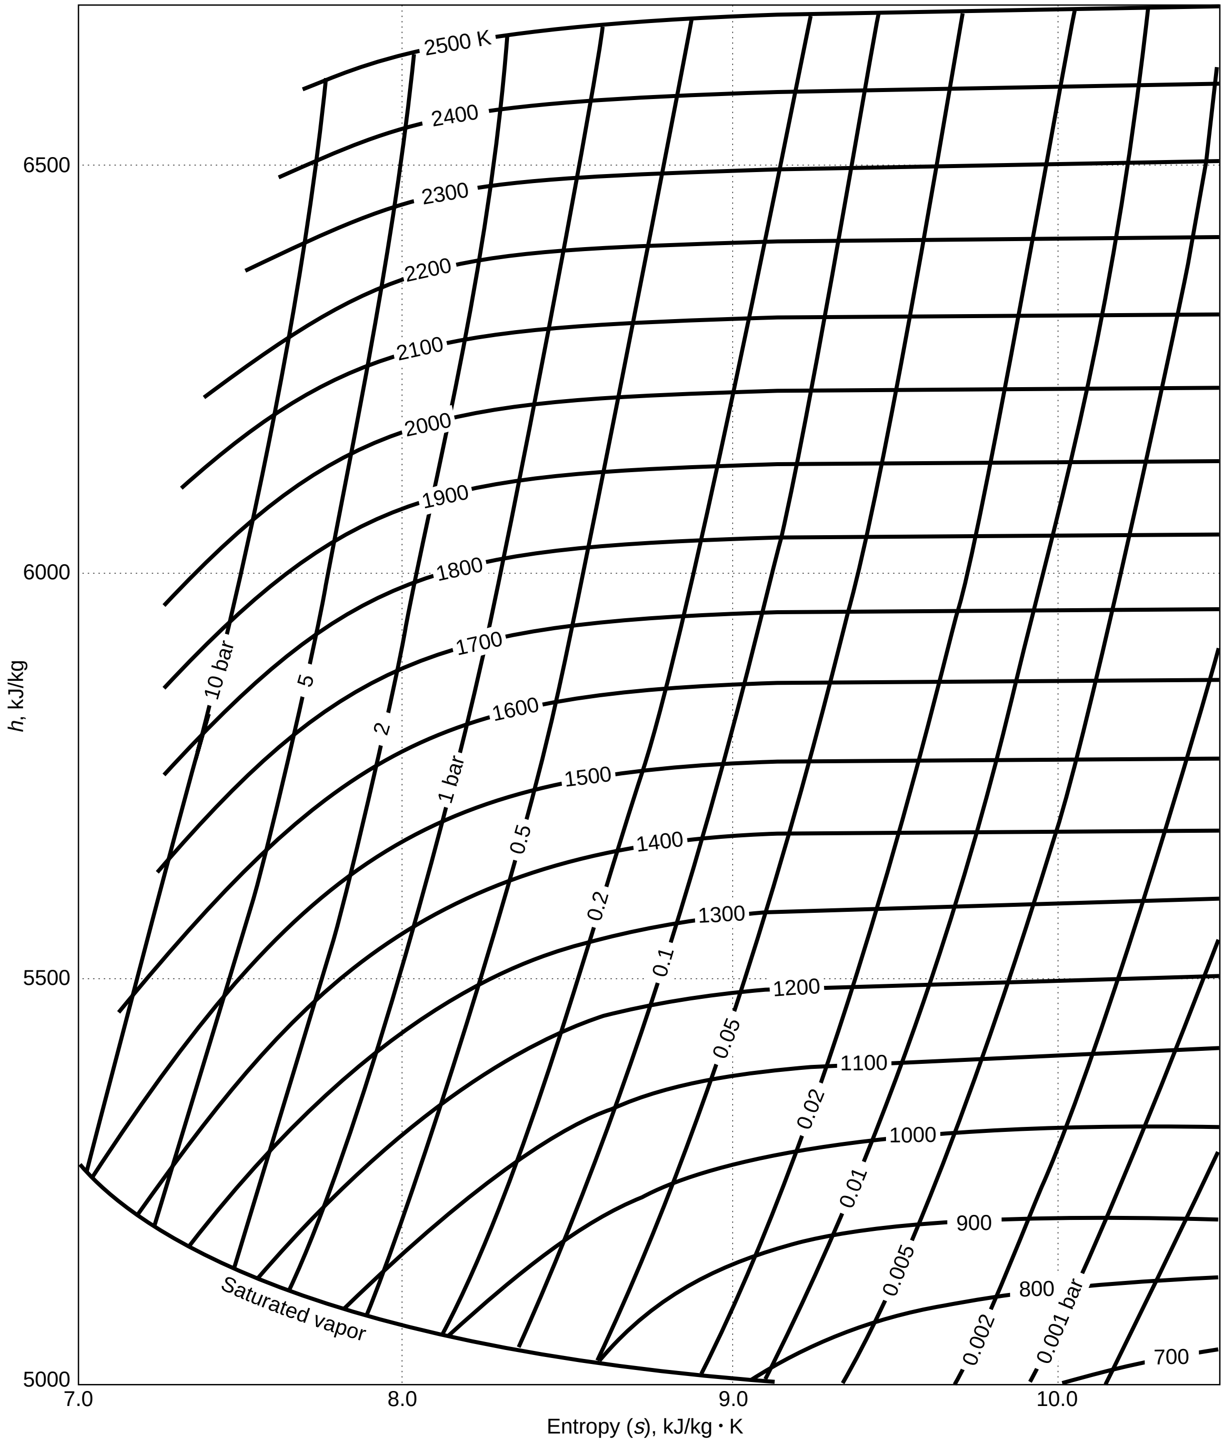

FIG. 2-28 Mollier Diagram for Sodium. Drawn from the Vargaftik et al. values in Ohse, R. W., *Handbook of Thermodynamic and Transport Properties of Alkali Metals,* Blackwell Sci. Pubs., Oxford, UK, 1985. These values are identical with those of Vargaftik, N. B., *Handbook of Thermophysical Properties of Gases and Liquids,* Moscow, 1972, and the Hemisphere translation, pp. 19. An apparent discontinuity exists between the superheat values and the saturation values, not reproduced here. For a Mollier diagram in f.p.s. units from 0.1 to 150 psia, 1500 to 2700°R, see Fig. 3-36, p. 3-232 of the 6th edition of this handbook. An extensive review of properties of the solid and the saturated liquid was given by Alcock, C. B., Chase, M. W. et al., *J. Phys. Chem. Ref. Data,* **23**(3), 385–497, 1994.

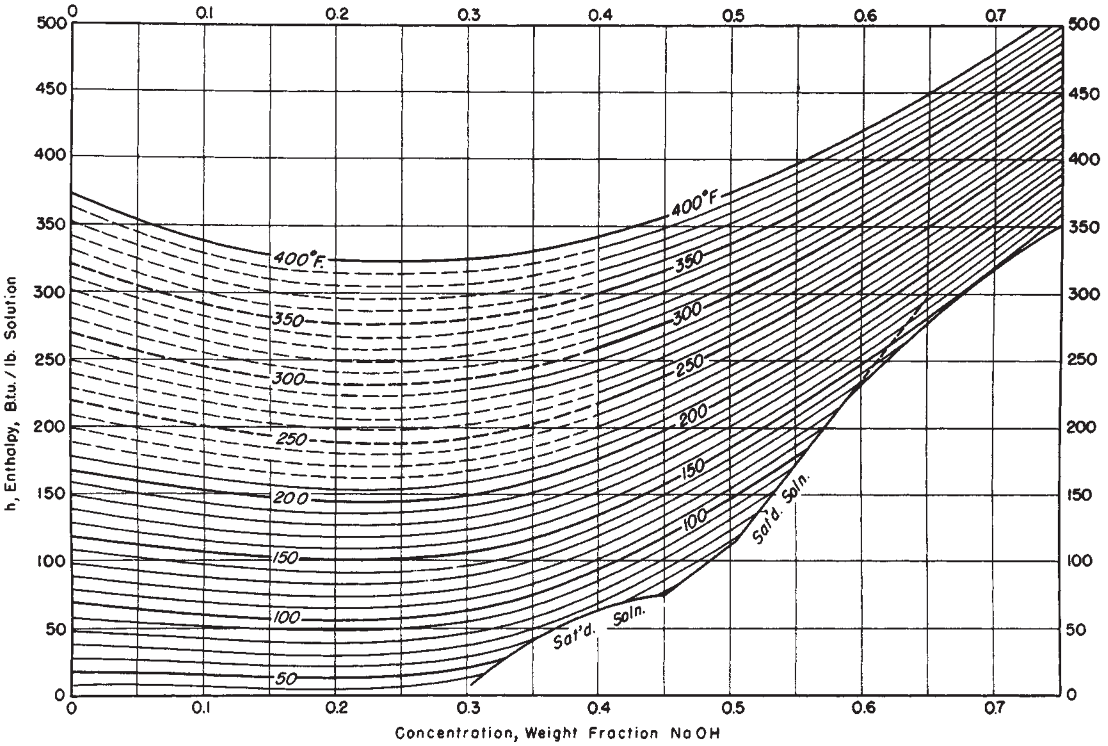

FIG. 2-29 Enthalpy-concentration diagram for aqueous sodium hydroxide at 1 atm. Reference states: enthalpy of liquid water at 32°F and vapor pressure is zero; partial molal enthalpy of infinitely dilute NaOH solution at 64°F and 1 atm is zero. [*McCabe,* Trans. Am. Inst. Chem. Eng., ***31,*** *129 (1935).*]

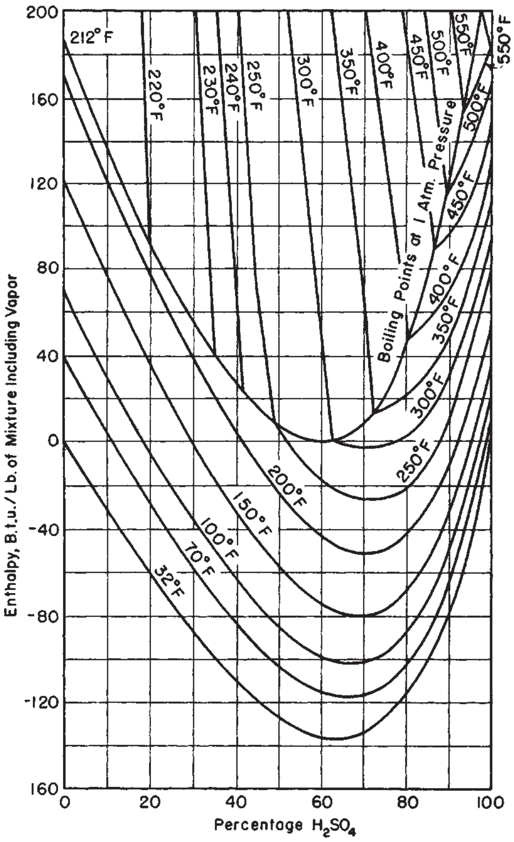

FIG. 2-30 Enthalpy-concentration diagram for aqueous sulfuric acid at 1 atm. Reference states: enthalpies of pure-liquid components at 32°F and vapor pressures are zero. NOTE: It should be observed that the weight basis includes the vapor, which is particularly important in the two-phase region. The upper ends of the tie lines in this region are assumed to be pure water. (*Hougen and Watson,* Chemical Process Principles, *part I, Wiley, New York, 1943.*)

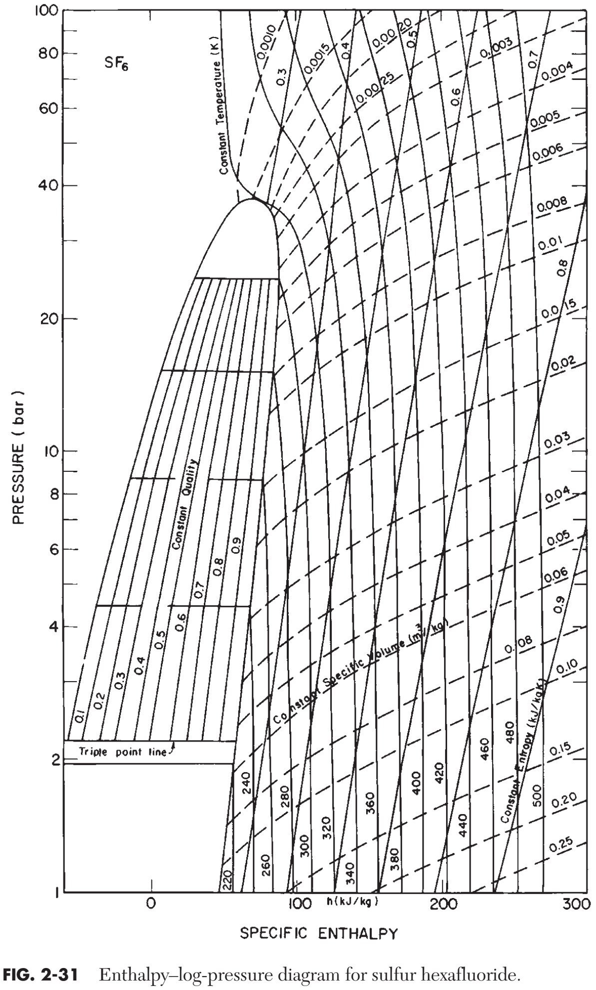

FIG. 2-31 Enthalpy–log-pressure diagram for sulfur hexafluoride.

TABLE 2-348 Saturated SUVA AC 9000

DuPont bulletin T–AC–9000–SI, 1994 (16 pp.) gives tables and a chart to 100 bar, 235°C. With a stated composition of 23% wt CH_2F_2 (R23), 25% wt CHF_2CF_3 (R125), and 52% wt CH_2FCH_3 (R134a) this is apparently identical to KLEA 66, to which the reader is referred.

*1 bar = 10^5 N/m^2.

†Above the solid line, the condensed phase is solid; below it, liquid.

‡Critical temperature.

NOTE: The notations 6.30.–11, 1.073.–3, 9.55.+9, etc. signify 6.30×10^{-11}, 1.073×10^{-3}, 955×10^9, etc.

Tables 2-351 and 2-352 are provided for general use. Tables to higher precision are available over certain ranges and for various properties. The most current internationally accepted tables are found in Haar, L., J. S. Gallagher, and G. S. Kell, *NBS/NRC Steam Tables,* Hemisphere, Washington, DC, 1984 (320 pp.). These do not tabulate certain properties at saturation states. A revised release on the IAPWS Skeleton Tables 1985 for the thermodynamic properties of ordinary water substance, Sept. 1993 (15 pp), is apparently the latest international publication. In *J. Phys. Chem. Ref. Data* **17,** 4 (1988): 1439–1540, H. Sato, M. Uematsu, and others review existing steam tables and present the 1985 formulation of skeleton tables. Property codes and programs include Cheng, S. C. and C. Nguyen, *Modeling and Simulation on Microcomputers 1989* (R. W. Allen, ed.), S.C.S. Intl., San Diego, 1989 (pp. 138–141); Garland, W. J. and B. J. Hand, *Nucl. Engng. & Des.,* **113,** (1989): 21–34; Dickey, D. S., *Chem. Eng.* **98,** 9 (1991): 207–8 and **98,** 11: 235–6; Muneer, T. and S. M. Scott, *Proc. Inst. Mech. Eng.,* **205,** (1991): 25–29; and *Energy Convsn. Mgmt.,* **31,** 4 (1991): 315–325. Useful pictorial representations of 20 properties as a function of both temperature (to 800°C) and pressure (to 1000 bar) are given by Grigull, U., J. Bach, et al., *Warme- u. Stoff.,* **1** (1968): 202–213. Property equations for the saturated liquid for the range 0–300°C are given by Charters, W. W. S. and H. A. Sadafi, *Rev. Int. Froid,* **10,** (Mar. 1987): 105–6. Gordon, S., NASA Tech. Paper 1906, 1982 gives detailed tables for ice from 0 K. Ice and snow properties are reviewed by Fukusako, S., *Int. J. Thermophys.,* **11,** 2 (1990): 353–372. See also Wagner, W., A. Saul, et al., *J. Phys. Chem. Ref. Data,* **23,** 3 (1994): 515–525, and Table 2-358.

Condensed from U. Grigull, Private communication, January 18, 1995.

Materials prepared at Technical University München, Germany by U. Grigull and S. Marek. For a table as a function of temperature, see Grigull, U. and S. Marek, *Warme u. Stoff.*, **30** (1994): 1–8.

t = the triple point (at 6.117×10^{-5} bar, 0.01°C); v_f = 0.0010021 m³/kg: $\alpha_f = -67.42 \times 10^{-6}$/K.

Other equations for properties are given by Jones, F. E. and G. L. Harris, *J. Res. N.I.S.T.*, **97,** 3 (1992): 335–340, and by Wagner, W. and A. Pruss, *J. Phys. Chem. Ref. Data*, **22,** 3 (1993): 783–787. Steam tables include Walker, W. A., U.S. Naval Ordn. Lab. rept. NOLTR NOLTR-66-217 = AD 651105 (0–1000 bar, 0–150°C), 1967 (72 pp.); Grigull, U., J. Straub, et al., *Steam Tables in S.I. Units* (0.01–1000 bar, 0–1000°C), Springer-Verlag, Berlin, 1990 (133 pp.); Tseng, C. M., T. A. Hamp, et al., Atomic Energy of Canada rept. (30 props, sat liq & vap., 1–220 bar), AECL-5910 1977 (90 pp.). For dissociation, see e.g., Knonicek, V., *Rozpr. Cesko Acad Ved., Rada techn ved* (0.01–100 bar, 1000–5000 K). **77,** 1 (1967). The proceedings of the 10th international conference on the properties of steam were edited by Sytchev, V. V. and A. A. Aleksandrov, Plenum, NY, 1984; and for the 11th conference by Pichal, M. and O. Sifner, Hemisphere, 1989 (550 pp.).

For electrical conductivity, see e.g., Marshall, W. L., *J. Chem. Eng. Data*, **32** (1987): 221–226.

*Values extracted and in some cases rounded off from those cited in Rabinovich (ed.), *Thermophysical Properties of Neon, Argon, Krypton and Xenon*, Standards Press, Moscow, 1976. This source contains values for the compressed state for pressures up to 1000 bar, etc. m = melting point; c = critical point. The notation 2.642.–4 signifies 2.642×10^{-4}. This book was published in English translation by Hemisphere, New York, 1988 (604 pp.).

*Values extracted and in some cases rounded off from those cited in Rabinovich (ed.), *Thermophysical Properties of Neon, Argon, Krypton and Xenon.* Standards Press, Moscow, 1976. This source contains an exhaustive tabulation of values. v = specific volume, m^3/kg; h = specific enthalpy, kJ/kg; s = specific entropy, kJ/(kg·K). The notation 2.776.–4 signifies 2.776×10^{-4}. This book was published in English translation by Hemisphere, New York, 1988 (604 pp.).

TRANSPORT PROPERTIES

INTRODUCTION

Extensive tables of the viscosity and thermal conductivity of air and of water or steam for various pressures and temperatures are given with the thermodynamic-property tables. The thermal conductivity and the viscosity for the saturated-liquid state are also tabulated for many fluids along with the thermodynamic-property tables earlier in this section.

UNITS CONVERSIONS

For this subsection the following units conversions are applicable:

Diffusivity: to convert square centimeters per second to square feet per hour, multiply by 3.8750; to convert square meters per second to square feet per hour, multiply by 38,750.

Pressure: to convert bars to pounds-force per square inch, multiply by 14.504.

Temperature: °F = 9⁄5 °C + 32; °R = 9⁄5 K.

Thermal conductivity: to convert watts per meter-kelvin to British thermal unit–feet per hour–square foot–degree Fahrenheit, multiply by 0.57779; and to convert British thermal unit–feet per hour–square foot–degree Fahrenheit to watts per meter-kelvin, multiply by 1.7307.

Viscosity: to convert pascal-seconds to centipoises, multiply by 1000.

ADDITIONAL REFERENCES

An extensive coverage of the general pressure and temperature variation of thermal conductivity is given in the monograph by Vargaftik, Filippov, Tarzimanov, and Totskiy, *Thermal Conductivity of Liquids and Gases* (in Russian), Standartov, Moscow, 1978, now published in English translation by CRC Press, Miami, FL.

For a similar work on viscosity, see Stephan and Lucas, *Viscosity of Dense Fluids,* Plenum, New York and London, 1979. Tables and polynomial fits for refrigerants in both the gaseous and the liquid state are contained in *ASHRAE Thermophysical Properties of Refrigerants,* American Society of Heating, Refrigerating and Ventilating Engineers, Atlanta, GA, 1993. Other sources for viscosity include Fischer & Porter Co. catalog 10-A-94, "Fluid densities and viscosities," 1953 (200 industrial fluids in 48 pp.) and van Velzen, D., R. L. Cardozo et al., EURATOM Ispra, Italy rept. 4735 e, 1972 (160 pp.). Liquid viscosity, 314 cpds, is summarized in *I&EC Fundtls.,* 11 (1972): 20–26. Five hundred forty-nine binary and ternary systems are discussed in Skubla, P., *Coll. Czech. Chem. Commun.,* **46** (1981): 303–339.

See also Duhne, C. R., *Chem. Eng.* (NY), **86,** 15 (July 16, 1979): 83–91 (equations and 326 liquids); and Rao, K. V. K., *Chem. Eng.* (NY), **90,** 11 (May 30, 1983): 90–91 (nomograph, 87 liquids). For rheology, non-Newtonian behavior, and the like, see, for instance, Barnes, H., *The Chem. Engr.* (UK), (June 24, 1993): 17–23; Hyman, W. A., *I&EC Fundtls.,* **16** (1976): 215–218; and Ferguson, J. and Z. Kemblowski, *Applied Fluid Rheology,* Elsevier, 1991 (325 pp.). Other sources for thermal conductivity include Ho, C. Y., R. W. Powell et al., *J. Phys. Chem. Ref. Data,* **1** (1972) and **3,** suppl. 1 (1974); Childs, Ericks et al., N.B.S. Monogr. 131, 1973; Jamieson, D. T., J. B. Irving et al., *Liquid Thermal Conductivity,* H.M.S.O., Edinburgh, Scotland, 1975 (220 pp.).

*An approximate interpolation scheme is to plot the logarithm of the viscosity or the thermal conductivity versus the logarithm of the absolute temperature. At 250 K the viscosity of gaseous argon is to be read as 1.95×10^{-5} Pa·s = 0.0000195 Ns/m^2.

TABLE 2-365 Viscosities of Liquids: Coordinates for Use with Fig. 2-33

Liquid	*X*	*Y*	Liquid	*X*	*Y*
Acetaldehyde	15.2	4.8	Freon-113	12.5	11.4
Acetic acid, 100%	12.1	14.2	Glycerol, 100%	2.0	30.0
Acetic acid, 70%	9.5	17.0	Glycerol, 50%	6.9	19.6
Acetic anhydride	12.7	12.8	Heptane	14.1	8.4
Acetone, 100%	14.5	7.2	Hexane	14.7	7.0
Acetone, 35%	7.9	15.0	Hydrochloric acid, 31.5%	13.0	16.6
Acetonitrile	14.4	7.4	Iodobenzene	12.8	15.9
Acrylic acid	12.3	13.9	Isobutyl alcohol	7.1	18.0
Allyl alcohol	10.2	14.3	Isobutyric acid	12.2	14.4
Allyl bromide	14.4	9.6	Isopropyl alcohol	8.2	16.0
Allyl iodide	14.0	11.7	Isopropyl bromide	14.1	9.2
Ammonia, 100%	12.6	2.0	Isopropyl chloride	13.9	7.1
Ammonia, 26%	10.1	13.9	Isopropyl iodide	13.7	11.2
Amyl acetate	11.8	12.5	Kerosene	10.2	16.9
Amyl alcohol	7.5	18.4	Linseed oil, raw	7.5	27.2
Aniline	8.1	18.7	Mercury	18.4	16.4
Anisole	12.3	13.5	Methanol, 100%	12.4	10.5
Arsenic trichloride	13.9	14.5	Methanol, 90%	12.3	11.8
Benzene	12.5	10.9	Methanol, 40%	7.8	15.5
Brine, $CaCl_2$, 25%	6.6	15.9	Methyl acetate	14.2	8.2
Brine, NaCl, 25%	10.2	16.6	Methyl acrylate	13.0	9.5
Bromine	14.2	13.2	Methyl *i*-butyrate	12.3	9.7
Bromotoluene	20.0	15.9	Methyl *n*-butyrate	13.2	10.3
Butyl acetate	12.3	11.0	Methyl chloride	15.0	3.8
Butyl acrylate	11.5	12.6	Methyl ethyl ketone	13.9	8.6
Butyl alcohol	8.6	17.2	Methyl formate	14.2	7.5
Butyric acid	12.1	15.3	Methyl iodide	14.3	9.3
Carbon dioxide	11.6	0.3	Methyl propionate	13.5	9.0
Carbon disulfide	16.1	7.5	Methyl propyl ketone	14.3	9.5
Carbon tetrachloride	12.7	13.1	Methyl sulfide	15.3	6.4
Chlorobenzene	12.3	12.4	Napthalene	7.9	18.1
Chloroform	14.4	10.2	Nitric acid, 95%	12.8	13.8
Chlorosulfonic acid	11.2	18.1	Nitric acid, 60%	10.8	17.0
Chlorotoluene, ortho	13.0	13.3	Nitrobenzene	10.6	16.2
Chlorotoluene, meta	13.3	12.5	Nitrogen dioxide	12.9	8.6
Chlorotoluene, para	13.3	12.5	Nitrotoluene	11.0	17.0
Cresol, meta	2.5	20.8	Octane	13.7	10.0
Cyclohexanol	2.9	24.3	Octyl alcohol	6.6	21.1
Cyclohexane	9.8	12.9	Pentachloroethane	10.9	17.3
Dibromomethane	12.7	15.8	Pentane	14.9	5.2
Dichloroethane	13.2	12.2	Phenol	6.9	20.8
Dichloromethane	14.6	8.9	Phosphorus tribromide	13.8	16.7
Diethyl ketone	13.5	9.2	Phosphorus trichloride	16.2	10.9
Diethyl oxalate	11.0	16.4	Propionic acid	12.8	13.8
Diethylene glycol	5.0	24.7	Propyl acetate	13.1	10.3
Diphenyl	12.0	18.3	Propyl alcohol	9.1	16.5
Dipropyl ether	13.2	8.6	Propyl bromide	14.5	9.6
Dipropyl oxalate	10.3	17.7	Propyl chloride	14.4	7.5
Ethyl acetate	13.7	9.1	Propyl formate	13.1	9.7
Ethyl acrylate	12.7	10.4	Propyl iodide	14.1	11.6
Ethyl alcohol, 100%	10.5	13.8	Sodium	16.4	13.9
Ethyl alcohol, 95%	9.8	14.3	Sodium hydroxide, 50%	3.2	25.8
Ethyl alcohol, 40%	6.5	16.6	Stannic chloride	13.5	12.8
Ethyl benzene	13.2	11.5	Succinonitrile	10.1	20.8
Ethyl bromide	14.5	8.1	Sulfur dioxide	15.2	7.1
2-Ethyl butyl acrylate	11.2	14.0	Sulfuric acid, 110%	7.2	27.4
Ethyl chloride	14.8	6.0	Sulfuric acid, 100%	8.0	25.1
Ethyl ether	14.5	5.3	Sulfuric acid, 98%	7.0	24.8
Ethyl formate	14.2	8.4	Sulfuric acid, 60%	10.2	21.3
2-Ethyl hexyl acrylate	9.0	15.0	Sulfuryl chloride	15.2	12.4
Ethyl iodide	14.7	10.3	Tetrachloroethane	11.9	15.7
Ethyl propionate	13.2	9.9	Thiophene	13.2	11.0
Ethyl propyl ether	14.0	7.0	Titanium tetrachloride	14.4	12.3
Ethyl sulfide	13.8	8.9	Toluene	13.7	10.4
Ethylene bromide	11.9	15.7	Trichloroethylene	14.8	10.5
Ethylene chloride	12.7	12.2	Triethylene glycol	4.7	24.8
Ethylene glycol	6.0	23.6	Turpentine	11.5	14.9
Ethylidene chloride	14.1	8.7	Vinyl acetate	14.0	8.8
Fluorobenzene	13.7	10.4	Vinyl toluene	13.4	12.0
Formic acid	10.7	15.8	Water	10.2	13.0
Freon-11	14.4	9.0	Xylene, ortho	13.5	12.1
Freon-12	16.8	5.6	Xylene, meta	13.9	10.6
Freon-21	15.7	7.5	Xylene, para	13.9	10.9

*Compiled by P. E. Liley from tables of specific heat at constant pressure, thermal conductivity, and viscosity given in SI units for integral kelvin temperatures and pressures in bars by Vasserman. *Thermophysical Properties of Air and Its Components* and *Thermophysical Properties of Liquid Air and Its Components.* Nauka, Moscow, and in translated form by the National Bureau of Standards, Washington. The number of significant figures given above reflects the similar numbers appearing for the constituent properties in the source references. While reasonable agreement occurs for atmospheric pressure with some other works, the fragmentary data available for the saturated, etc., states show large deviations.

*Dashes indicate inaccessible states. Average uncertainty is about 20 percent. Values derived from formulations for thermal conductivity, specific heat at constant pressure, and viscosity contained in *Thermophysical Properties of Refrigerants.* American Society of Heating, Refrigerating and Air-Conditioning Engineers, New York, 1976. For further details see M. W. Johnson, M.S.M.E. thesis, Purdue University, West Lafayette, Ind., 1976.

In this table are a representative selection of diffusion coefficients. The subsection "Prediction and Correlation of Physical Properties" should be consulted for estimation techniques. As general references, the works by Hirschfelder, Curtiss, and Bird, *Molecular Theory of Gases and Liquids,* Wiley, New York, 1964; Chapman and Cowling, *The Mathematical Theory of Non-Uniform Gases,* Cambridge, New York, 1970; Reid and Sherwood, *The Properties of Gases and Liquids,* McGraw-Hill, New York, 1964; and Bretsznajder, *Prediction of Transport and Other Physical Properties of Fluids,* Pergamon, New York, 1971, may be found useful. The most exhaustive recent compilation for gases is by Mason and Marrero, *J. Phys. Chem. Ref. Data,* **1** (1972). Unfortunately, the Mason and Marrero work cites only equations and equation constants and not direct tabulations. For these, the Landolt-Börnstein series is suggested.

TABLE 2-372 Diffusivities in Liquids (25°C)

Dilute solutions and 1 atm unless otherwise noted; use $D_L\mu/T$ = constant to estimate effect of temperature; * indicates that reference gives effect of concentration.

Zirconium	100	110	59	42	38	34	25	23	22	21	21				

* Especially at low temperatures, the thermal conductivity can often be markedly reduced by even small traces of impurities. This table, for the highest-purity specimens available, should thus be used with caution in applications with commercial materials. From Perry, *Engineering Manual,* 3d ed., McGraw-Hill, New York, 1976. A more detailed table appears as Section 5.5.6 in the *Heat Exchanger Design Handbook,* Hemisphere Pub. Corp., Washington, DC, 1983.

† Parallel to basal plane.

‡ Perpendicular to basal plane.

§ Also known as Teflon, etc.

Sandstone	2150	0.59	0.745	2.9	1.8
Silica		0.79	0.743	1.3	
Sapphire	3975	0.48	0.765	46	15
Silicon carbide	3160	0.86	0.675	490	230
Soil	2050	0.38	1.84	0.52	0.14
Teflon	2200	0.92	0.35	0.26	0.34
Thoria	4160	0.28	0.71	14	4.7
Urethane foam	70		1.05	0.03	0.36
Vermiculite	120		0.84	0.06	0.60

NOTE: Difficulties of accurately characterizing many of the specimens mean that many of the values presented here must be regarded as being of order of magnitude only. For some materials, actual measurement may be the only way to obtain data of the required accuracy. To convert kilograms per cubic meter to pounds per cubic foot, multiply by 0.062428; to convert kilojoules per kilogram-kelvin to British thermal units per pound-degree Fahrenheit, multiply by 0.23885.

PREDICTION AND CORRELATION OF PHYSICAL PROPERTIES

INTRODUCTION

In the absence of reliable experimental data, the methods presented here provide physical property estimates that are sufficiently accurate for many engineering applications. These techniques have been selected on the basis of accuracy, generality, and, in most cases, simplicity; they are divided into 11 categories: (1) pure component constants: critical properties, normal freezing and boiling temperatures, acentric factor, radius of gyration, dipole moment, and van der Waals area and volume; (2) vapor pressure; (3) ideal gas thermal properties: heat capacity and enthalpy, Gibbs energy, and entropy of formation; (4) enthalpy of vaporization and fusion; (5) solid and liquid heat capacity; (6) vapor, liquid, and solid density; (7) vapor and liquid viscosity; (8) vapor and liquid thermal conductivity; (9) vapor and liquid diffusivity; (10) surface tension; and (11) flammability properties: flash point, flammability limits, and autoignition temperature. The definition of the property and limitations and accuracy of each method of correlation or prediction are given for each property. Numerical examples are included for many of the methods. Equation symbols are listed under "Nomenclature," and literature citations, indicated by superscript numbers, follow the nomenclature under "References." Essentially all of the methods are derived from work on the *American Petroleum Institute Technical Data Book*[23] (hydrocarbon compounds and their mixtures), the AIChE Design Institute for Physical Property Data (DIPPR) *Data Prediction Manual*[22] (nonhydrocarbon compounds and their mixtures), and the DIPPR Data Compilation Project[24].

UNITS

Applicable dimensional units are shown individually with each equation. The International Metric System (SI) is used when feasible; otherwise commonly used U.S. engineering units are employed. The reader is referred to Sec. 1 for unit conversion factors.

Nomenclature

Symbol	Definition	SI units	U.S. customary units
B	Second virial coefficient	m^3/kmol	ft^3/lbmol
C_p	Heat capacity at constant pressure	J/(kmol·K)	Btu/(lbm °F)
C_v	Heat capacity at constant volume	kg/m^3	lbm/ft^3
d	Mass density	m^2/s	ft^2/s
D	Diffusivity		
F	Conductivity factor in Eq. (2-136)		
k	Thermal conductivity	W/(m·K)	Btu/(h·ft °F)
K	Watson/UOP characterization factor = $(1.8T_b)^{1/3}$/rel den		
ln	Denotes natural logarithm		
M	Molecular weight		
$MeABP$	Mean average boiling point		
N	Carbon number		
N_A	Avogadro's number		
P	Pressure	Pa	lbf/in^2
P^{sat}	Vapor pressure	Pa	lbf/in^2
$[P]$	Parachor		
rel den	Relative density at 15°C and 0.1 MPa		
R	Universal gas constant; e.g., 8314 Pa·m^3/kmol K		
$\overline{R}$	Radius of gyration		
S	Absolute entropy	J/kg	Btu/lbm
T	Absolute temperature	K	R
V	Molar volume	m^3/kmol	ft^3/lbmole
x	Mole fraction of component in liquid phase		
y	Mole fraction of component in vapor phase		
Z	Compressibility factor = PV/RT		
	Greek symbols		
ΔG_f	Gibbs energy of formation	J/kg	Btu/lbm
ΔH_f	Enthalpy (heat) of formation	J/kg	Btu/lbm
ΔH_{fus}	Enthalpy (heat) of fusion	J/kg	Btu/lbm
ΔH_V	Enthalpy (heat) of vaporization	J/kg	Btu/lbm
ΔS_f	Entropy of formation	J/(kg·K)	Btu/lbm
ΔS_{fus}	Entropy of fusion	J/(kg·K)	Btu/lbm
ΔZ_V	Difference of vapor and liquid compressibility factors defined in Eq. (2-55)		
Θ	T_b/T_c		
λ	Dipole moment		
μ	Absolute viscosity	Pa·s	lbm/(ft·s)
ν	Kinematic viscosity	m^2/s	ft^2/s
ρ	Molar density	kmol/m^3	lb·mole/ft^3
σ	Surface tension	N/m	dyne/cm
ϕ	Volume fraction		
ω	Acentric factor		
	Superscripts		
r	At reference condition		
(0)	Simple spherical molecule, corresponding states		
(1)	Correction factor, corresponding states		
°	Of the ideal gas		
′	At atmospheric pressure		
	Subscripts		
b	At normal boiling temperature		
bp	At bubble point		
c	At critical point		
G	Of the gas/vapor		
HI	Upper limit		
i	Component index, of the ith component		
j	Component index, of the jth component		
L	Of the liquid		
m	Of the mixture		
mc	Mixture correspondence		
mlt	At melting temperature		
o	Of organic component		
pc	Pseudocritical quantity		
r	Reduced quantity		
RA	Rackett parameter		
sat	Saturated		
S	Of the solid		
V	Of the vapor		
w	Of water

PURE COMPONENT CONSTANTS

Basic pure component constants required to characterize components or mixtures for calculation of other properties include the melting point, normal boiling point, critical temperature, critical pressure, critical volume, critical compressibility factor, acentric factor, and several other characterization properties. This section details for each property the method of calculation for an accurate technique of prediction for each category of compound, and it references other accurate techniques for which space is not available for inclusion.

Critical Temperature The critical temperature of a compound is the temperature above which a liquid phase cannot be formed, no matter what the pressure on the system. The critical temperature is important in determining the phase boundaries of any compound and is a required input parameter for most phase equilibrium thermal property or volumetric property calculations using analytic equations of state or the theorem of corresponding states. Critical temperatures are predicted by various empirical methods according to the type of compound or mixture being considered.

For **pure hydrocarbons,** the method of Ambrose[2] is the most accurate and will also be useful for predicting critical pressure and volume. Equation (2-1) requires only the normal boiling point, T_b, and the molecular structure of the compound.

$$T_c = T_b\left[1 + \frac{1}{1.242 + \sum \Delta_T - 0.023\Delta(\text{Platt no.})}\right] \tag{2-1}$$

T_c and T_b are the critical and normal boiling temperatures, respectively, expressed in kelvins. Values of Δ_T from Table 2-383 are summed for each part of the molecule to yield $\sum \Delta_T$ (e.g., for isobutane, $3 \times —CH_3 + 1 \times >CH—$). Δ(Platt no.) is equal to the Platt number of any alkyl chains in the molecule minus the Platt number of the *n*-alkane with the same number of carbon atoms. The Platt number is defined as the number of pairs of carbon atoms that are separated by three carbon-carbon bonds and is an indicator of branching (e.g., for 2,2,3-trimethylpentane, the Platt number is 5). The Platt number of an *n*-alkane is the number of carbon atoms minus three (e.g., for *n*-octane, the Platt number is five). Errors in T_c average about 4 K for paraffins to C_{20} and other hydrocarbons to C_{14}.

Equation (2-2), another somewhat simpler method for estimating the critical temperature of pure hydrocarbons only, is the method of Nokay[76] and requires the normal boiling point, the relative density, and the compound family.

$$\log T_c = A + B \log_{10}(\text{rel den}) + C \log T_b \tag{2-2}$$

T_c and T_b are the critical and normal boiling temperatures, respectively, expressed in kelvins. The relative density (rel den) of the liquid at 15°C is 0.1 MPa. The regression constants *A, B,* and *C* are tabulated by family in Table 2-384. Errors average about 3 K.

For **pure nonhydrocarbon organics,** the most accurate method for prediction of critical temperature for all compound groups is also the Ambrose[2] method. Equation (2-1) applies to all nonhydrocarbon compounds except perfluorocarbons, where the constant 1.242 is replaced by 1.570. For compounds containing any of C, H, O, N, S, or halogens up to C_{13} and ranging in critical temperature from 228–790 K, the average error is about 6 K.

Alternate methods for nonhydrocarbon organics are the first order method of Lydersen[63] with an average error of 9 K although the method of Ambrose is considerably better for alcohols and ketones.

Equation (2-3) is the Lydersen equation for critical temperature and requires only the normal boiling point and the molecular structure for solution.

$$T_c = \frac{T_b}{[0.567 + \sum \Delta_T - (\sum \Delta_T)^2]} \tag{2-3}$$

Contributions to $\sum \Delta_T$ are given in Table 2-385.

For **pure inorganic compounds,** the method of Gambill[31] was modified to yield Eq. (2-4) and only requires the normal boiling point as input.

$$T_c = 1.64 T_b \tag{2-4}$$

Although this equation was tested with available experimental data (38 compounds), it can only be considered a rough approximation. **Inorganic-organic** and **inorganic-halide** compounds are predicted better by replacing the constant 1.64 in Eq. (2-4) by 1.55.

For both **hydrocarbons** and **nonhydrocarbon organic defined mixtures,** the method of Li[60] is used with a relatively simple volumetric average mixing rule as shown in Eq. (2-5) to calculate the true critical temperature.

$$T_{cm} = \sum_j \left(\frac{y_j V_{c_j}}{\sum_i y_i V_{c_i}}\right) T_{c_j} \tag{2-5}$$

T_{cm} is the mixture critical temperature in K. V_c is the critical volume of a component, m^3/kmole. The mole fraction of a component is *y.* The mixture contains *i* components.

For hydrocarbon systems, the average error is about 3 K, while for systems containing nonhydrocarbons, the average error is 15 K with the highest errors occurring where simple gases are present. The method of Chueh and Prausnitz[18] yields average errors slightly lower than the method of Li, but it is computationally more complex.

Critical Pressure The critical pressure of a compound is the vapor pressure of the compound at the critical temperature. Below the critical temperature, any compound above its vapor pressure will be a liquid. The critical pressure is required for calculations discussed in the part of the section on critical temperature.

For **pure hydrocarbons,** the method of Ambrose[2] is the most accurate. Equation (2-6) requires only the molecular weight (*M*) and the molecular structure of the compound.

$$P_c = \frac{0.101325M}{[0.339 + \sum \Delta_P - 0.026\Delta(\text{Platt no.})]^2} \tag{2-6}$$

P_c is the critical pressure, MPa. Values of Δ_P from Table 2-383 are summed for each part of the molecule to yield $\sum \Delta_P$. Calculation of the Platt number is discussed under “Critical Temperature.” Errors in P_c average 0.07 MPa and are less reliable for compounds with 12 or more carbon atoms.

Corrections				If one of the ortho pair is —OH	−0.080	0	
benzene	0.448	0.924					
pyridine	0.448	0.850					
—OH	0.198	−0.025					
C_4H_4 (fused ring)	0.220	0.515					
—F	0.080	0.183					

*Group contributions for >CH and  in fused rings have been calculated from minimal data and may be less reliable than the other values.

Substituent increments do not apply to halogens.
Eq. (*a*): Δ_T (—OH) = $0.87 - 0.11n + 0.003n^2$
Eq. (*b*): Δ_p (—OH) = $0.100 - 0.013n$
n = carbon number of compound. For branched alcohols, an effective carbon number can be determined by interpolation between the normal alcohol of the same carbon number and the immediately lower normal alcohol using normal boiling points. (See Example 1.)

TABLE 2-384 Nokay Equation

Type compound	*A*	*B*	*C*
Paraffin	1.35940	0.43684	0.56224
Naphthene	0.65812	−0.07165	0.81196
Olefin	1.09534	0.27749	0.65563
Acetylene	0.74673	0.30381	0.79987
Diolefin	0.1384	−0.39618	0.99481
Aromatic	1.0615	0.22732	0.66929

Example 1 Estimate the critical temperature and critical pressure of 2-butanol using the Ambrose method, Eqs. (2-1) and (2-6). The experimental normal boiling point is 372.7 K.

$$T_c = T_b\left[1 + \frac{1}{1.242 + \sum \Delta_T - 0.023\Delta\ (\text{Platt no.})}\right]$$

$$P_c = \frac{0.101325M}{[0.339 + \sum \Delta_P - 0.026\Delta\ (\text{Platt no.})]^2}$$

Determine group contributions from Table 2-383 for a structure $CH_3CHOHCH_2CH_3$:

Group	Number of groups	Δ_T	Δ_P
—CH_3	2	0.138	0.2260
>CH_2	1	0.138	0.2260
>CH−	1	0.095	0.2200
—OH	1	(a)	(b)

$\Delta_T°$(—OH) = $0.87 - 0.11(n) + 0.003\ n^2 = 0.558$
$\Delta_p°$(—OH) = $0.100 - 0.013(n) = 0.0597$

To determine n, the normal boiling points of 1-propanol (370.3 K) and 1-butanol (390.9 K) are required:

$$n = 3 + \left(\frac{372.7 - 370.3}{390.9 - 370.3}\right)(4 - 3) = 3.1$$

The Platt number of the compound is determined by substituting a CH_3 group for the OH.

$$CH_3\text{—}CH(CH_3) - CH_2CH_3,\ \text{Platt no.} = 2$$

The Platt number of the n-alkane of the same carbon number is $5 - 3 = 2$. Thus, Δ(Platt no.) = $2 - 2 = 0$. Therefore:

$$\sum \Delta_T = 2(.138) + .138 + .095 + .558 = 1.067$$

$$T_c = 372.7\left[1 + \frac{1}{1.242 + 1.067 - 0}\right]$$

$$T_c = 534.1\ \text{K}$$

An accurate experimental value is 536.05 K.

$$\sum \Delta_P = 2(.226) + .226 + .220 + .0597 = 0.9577$$

$$P_c = \frac{.101325(74.12)}{(.339 + .9577 - 0)^2}$$

$$P_c = 4.467\ \text{MPa}$$

An accurate experimental value is 4.179 MPa.

For **pure nonhydrocarbon organics,** the simplest accurate method for prediction of critical pressure is the method of Lydersen.[63] Equation (2-7) requires the molecular weight (M) and the molecular structure of the compound.

$$P_c = \frac{0.101325M}{(0.34 + \sum \Delta_P)^2} \tag{2-7}$$

P_c is the critical pressure, MPa. Values of Δ_P from Table 2-385 are summed to yield $\sum \Delta_P$. The average error in P_c is about 0.2 MPa when tested on compounds ranging in carbon number from C_1 to C_{10}.

Example 2 Estimate the critical temperature and critical pressure of 2-butanol, which has an experimental normal boiling point of 372.7 K. Use the Lydersen method, Eqs. (2-3) and (2-7).

The structure of 2-butanol is $CH_3CHOHCH_2CH_3$. Determine group contributions from Table 2-385.

Group	Number of groups	Δ_T	Δ_P
—CH_3	2	0.020	0.227
—CH_2—	1	0.020	0.227
—CH— (with | below)	1	0.012	0.210
—OH	1	0.082	0.06
		$\sum$ 0.154	0.951

$$T_c = \frac{T_b}{0.567 + \sum \Delta_T - (\sum \Delta_T)^2} = \frac{372.7}{.567 + .154 - (.154)^2}$$

$$T_c = 534.5\ \text{K}$$

The accurate experimental critical temperature is 536.05 K.

$$P_c = \frac{0.101325M}{(0.34 + \sum \Delta_P)^2} = \frac{(0.101325)(74.12)}{(0.34 + 0.951)^2}$$

$$P_c = 4.506 \text{ MPa}$$

The accurate experimental critical pressure is 4.179 MPa. No known method is available to predict the critical pressure of inorganic compounds.

For both **hydrocarbon** and **nonhydrocarbon organic defined mixtures,** the method of Kreglewski and Kay[52] is recommended. The critical temperature, critical pressure, and acentric factor of each compound and the critical temperature of the mixture must be known or predicted from the methods of this section.

$$P_{cm} = P_{pc} + P_{pc}\left[5.808 + 4.93\left(\sum_{i=1}^{n} x_i\omega_i\right)\right]\left[\frac{T_{cm} - T_{pc}}{T_{pc}}\right] \tag{2-8}$$

Use of Eq. (2-8) requires the pseudocritical properties defined by Eqs. (2-9) and (2-10)

$$T_{pc} = \sum_{i=1}^{n} x_i T_{c_i} \tag{2-9}$$

$$P_{pc} = \sum_{i=1}^{n} x_i P_{c_i} \tag{2-10}$$

Each component i of the mixture must have available its T_c, P_c, and ω. T_{cm} can be predicted from Eq. (2-5). For hydrocarbon systems, average errors in predicted critical pressures are about 0.2 MPa, except when organic gases are present and errors are unacceptably large. Errors for nonhydrocarbon organics not including inorganic gases average 0.5 MPa.

Critical Volume The critical volume of a compound is the volume occupied by a set mass of a compound at its critical temperature and pressure. While useful in itself, the critical volume is extensively used in equations for estimating volumetric fractions.

For **pure hydrocarbons,** two methods are quite accurate. The Ambrose[2] method used for T_c and P_c is also used for critical volume. Eq. (2-11) only requires the molecular structure of the compound.

$$V_c = 10^{-3}(40 + \sum \Delta_V) \tag{2-11}$$

V_c is the critical volume, m^3/kmole. Values of Δ_V are given in Table 2-383.

The average error for hydrocarbons of twelve or less carbon atoms is about 0.01 m^3/kmole.

The Riedel method[90] requires the critical temperature (T_c), critical pressure (P_c), and acentric factor (ω) of the compound as given by Eqs. (2-12) and (2-13). If the gas constant is in Pa·m^3/kmole·K, the critical volume will be in m^3/kmole.

$$V_c = \frac{RT_c}{P_c[3.72 + 0.26(\alpha - 7.00)]} \tag{2-12}$$

$$\alpha = 5.811 + 4.919\omega \tag{2-13}$$

The average error for paraffins up to C_{18} and other hydrocarbon families up to C_{11} is about 0.015 m^3/kmole. If estimated values of T_c and P_c are used, errors may be higher.

For **pure nonhydrocarbon organics,** the method of Fedors,[29] which requires only molecular structure, is the most accurate. Equation (2-14) shows the method to depend only on the molecular structure. The resulting V_c will be in m^3/kmole.

$$V_c = 0.0266 + \sum \Delta_V \tag{2-14}$$

Values for Δ_V are given in Table 2-386. The average error for compounds up to C_7 is about 0.007 m^3/kmole, although a maximum error of 0.03 m^3/kmole has been noted. No experimental data above C_7 are available for comparison.

Example 3 Estimate the critical volume of 2-butanol. Use the method of Fedors, Eq. (2-14).

$$V_c = 0.0266 + \sum \Delta_V$$

The molecular formula is $C_4H_{10}O$. Using the atomic contribution values from Table 2-386.

$$\sum \Delta_V = 4(.034426) + 10(.009172) + 1(.018000)$$
$$\sum \Delta_V = 0.2474$$
$$V_c = 0.0266 + 0.2474 = 0.2740 \text{ m}^3\text{/kmole}$$

The accurate experimental critical volume is 0.2690 m^3/kmole.

TABLE 2-386 Atomic and Structural Contributions for the Fedors Method

Atomic increments		Structural increments	
Atom	Δ_V	Feature	Δ_V
C	0.034426	Cl	0.052801
H	0.009172	Br	0.071774
O	0.020291	I	0.096402
O (alcohols)	0.018000	S	0.050866
N	0.048855	3-membered ring	−0.105824
N (amines)	0.047422	4-membered ring	−0.017247
F	0.022242	5-membered ring	−0.039126
		6-membered ring	−0.039508
Si	0.086174	double bond	+0.005028
$Si_{siloxane}$	0.126483	triple bond	+0.000797
$Si_{cyclic\ siloxane}$	0.126483	ring attached directly to another ring	+0.035524

The method of Lydersen[63] may also be used for prediction of critical volume, but it is not so accurate as the method of Fedors. Equation (2-15) depends only on molecular structure and gives a critical volume in m^3/kmole.

$$V_c = 0.040 + \sum \Delta_V \tag{2-15}$$

Group contributions for Δ_V are given in Table 2-385. Errors average about 0.01 m^3/kmole.

There is no known method for predicting the critical volume of inorganic compounds.

For both **hydrocarbon** and **nonhydrocarbon organic defined mixtures,** the method of Chueh and Prausnitz[19] is useful. For hydrocarbon systems, the mixing rule is shown by Eq. (2-16) for binaries and by Eq. (2-17) for multicomponents. Equations (2-18) through (2-20) give the input parameters. The mixture critical volume V_{cm} is a function of the pure component critical volumes. The constant C is zero for hydrocarbon systems and 0.1559 for systems containing a nonhydrocarbon gas.

$$V_{cm} = \phi_1 V_{c1} + \phi_2 V_{c2} + 2\phi_1\phi_2\nu_{12} \tag{2-16}$$

$$V_{cm} = \sum_{i}^{n}\sum_{j}^{n} \phi_i\phi_j\nu_{ij} \qquad (i \neq j) \tag{2-17}$$

$$\phi_j = \frac{x_j V_{cj}^{2/3}}{\sum_{i=1}^{n} x_i V_{ci}^{2/3}} \tag{2-18}$$

$$\nu_{ij} = \frac{V_{ij}(V_{ci} + V_{cj})}{2.0} \tag{2-19}$$

$$V_{ij} = -1.4684\left(\left|\frac{V_{ci} - V_{cj}}{V_{ci} + V_{cj}}\right|\right) + C \tag{2-20}$$

Errors average about 10 percent for systems containing hydrocarbons.

Systems containing only organics or organics and gases may give very high errors. A specialized modification of the method (Chueh and Prausnitz[18]) is available for binary mixtures containing organics but may give errors over 20 percent.

Critical Compressibility Factor The critical compressibility factor of a compound is calculated from the experimental or predicted values of the critical properties by the definition, Eq. (2-21).

$$Z_c = \frac{P_c V_c}{RT_c} \tag{2-21}$$

Critical compressibility factors are used as characterization parameters in corresponding states methods (especially those of Lydersen) to predict volumetric and thermal properties. The factor varies from about 0.23 for water to 0.26–0.28 for most hydrocarbons to slightly above 0.30 for light gases.

Normal Freezing Temperature (Melting Point) The melting point is the temperature at which melting occurs at atmospheric pressure. In most cases, measurements are made in air, making values slightly lower than if the measurements were made in vacuum. Impurities can cause a substantial decrease in the measured melting point. The melting point is very slightly higher than the triple point temperature—the temperature at which equilibrium exists between solid, liquid, and vapor—for a pure compound. For practical purposes, the two temperatures are equal. Reliable methods for predicting melting points have not until recently been advanced. Constantinou and

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Gani[20] derived a group contribution method that shows promise. Initial evaluations show average errors of 5 to 10 percent (10–30 K) on a wide variety of compounds, but larger errors can occur. It is recommended that several compounds of known melting point in the same or a similar family be predicted in order to estimate the probable error.

Normal Boiling Temperature The normal boiling temperature (point) is the temperature at which the vapor pressure equals exactly 101,325 Pa (1 atmosphere). Caution should be taken in using values from older references, where the temperature may be reported for the prevailing pressure (0.95–0.97 atm) rather than at 1 atmosphere. If at least two values of vapor pressure very close to 1 atmosphere are available, the normal boiling point can be interpolated or extrapolated on a plot of $\log P^{sat}$ vs. $1/T$. The section on vapor pressure discusses this in more detail.

Various methods are available for estimation of the normal boiling point of organic compounds. Lyman et al.[64] review and give calculational procedures for the methods of Meissner, Miller, and Lydersen/Forman-Thodos. A more recent method that has been determined to be more accurate is the method of Pailhes,[80] which requires one experimental vapor pressure point and Lydersen group contributions for critical temperature and critical pressure (Table 2-385).

$$T_b = T\,\frac{\log P_c + (1-\Theta)\log(1/p)}{\log P_c} \tag{2-22}$$

where T and p = the one low pressure vapor pressure point, in K and atm, respectively

$\Theta = T_c/T_b$ calculated from Eq. (2-3) using Lydersen contributions

P_c = critical pressure calculated from Eq. (2-7) using Lydersen contributions

A recent study of the method on a wide variety of complex organics shows an overall average error of less than 2 percent (~10 K). If no vapor pressure point is available, the new group contribution method of Constantinou and Gani[20] discussed under the section on melting point gives an overall average error of about 4 percent (~20 K) and may be useful. The method of Miller (Lyman et al.[64]), which requires only the molecular structure, has also been found to be relatively accurate for organics.

Example 4 Estimate the normal boiling point of 2-butanol. One vapor pressure point of 0.802 psia at 100°F is available.

Use the Pailhes method, Eq. (2-22).

$$T_B = T\,\frac{\log P_c + (1-\theta)\log(1/p)}{\log P_c}$$

From Example 2, P_c = 4.506 MPa; $\theta = T_c/T_b = 1.434$; T = 100°F = 310.9 K; and p = 0.802 psia = 5528 Pa.

$$T_b = (310.9)\,\frac{\log(4.506\times10^6) + (1-1.434)\log(1/5528)}{\log(4.506\times10^6)}$$

$$T_b = (310.9)(1.244) = 386.8 \text{ K}$$

An accepted experimental normal boiling point is 372.7 K.

Note the error here is 3.8 percent, a value above the average. If the vapor pressure point available would have been closer to one atmosphere, the error would have been much lower.

Acentric Factor The acentric factor of a compound (ω) is primarily a measure of the shape of a molecule, though it also measures a molecule's polarity. It is calculated from the reduced vapor pressure (P_r^{sat}) at a reduced temperature of 0.7 by the definition, Eq. (2-23).

$$\omega = -\log(P_r^{sat})_{T_r=0.7} - 1.000 \tag{2-23}$$

Critical temperature and pressure are required and can be estimated from the methods of this section. Vapor pressure is predicted by the methods of the next section. Experimental values should be used if available. The acentric factor is used as a third parameter with T_c and P_c in Pitzer-type corresponding states methods to predict volumetric properties and in cubic equations of state such as the Redlich-Kwong-Soave and Peng-Robinson equations. For simple spherical molecules, the acentric factor is essentially zero, rising as branching and molecular weight increases. For compounds of similar size and shape the acentric factor increases slightly with increasing polarity.

For mixtures, the acentric factor is usually taken as a simple molar average value of the n components of the mixture.

$$\omega = \sum_{i=1}^{n} x_i\omega_i \tag{2-24}$$

Miscellaneous Characterizing Constants The radius of gyration ($\overline{R}$) is a simultaneous size-shape factor varying with the manner in which mass is distributed about the center of gravity of the molecule. For planar molecules, the radius of gyration is

$$\overline{R} = \sqrt{\frac{(AB)^{1/2}N_A}{M}} \tag{2-25}$$

For three-dimensional molecules, it is

$$\overline{R} = \sqrt{\frac{(ABC)^{1/3}2\pi N_A}{M}} \tag{2-26}$$

AB and ABC are the products of the principal moments of inertia. Moments of inertia are calculated from bond angles and bond lengths. Many values are given by Landolt-Bornstein.[53] N_A is Avogadro's number, and M is the molecular weight of the molecule. Stuper et al.[105] give a computerized method for prediction of the radius of gyration.

The dipole moment (λ) of a molecule is the first moment of the electric charge density of a molecule. Paraffins have dipole moments of zero, while dipole moments of almost all hydrocarbons are small. McClellan[68] lists many dipole moments. The computer method of Dixon and Jurs[27] is the most useful method for predicting dipole moments. Lyman et al.[64] give other methods of calculation.

The van der Waals volume and area are characterizing parameters relating molecular configurations. Bondi[8] describes group contribution methods for their calculation.

VAPOR PRESSURE

Vapor pressure is the most important of the basic thermodynamic properties affecting liquids and vapors. The vapor pressure is the pressure exerted by a pure component at equilibrium at any temperature when both liquid and vapor phases exist and thus extends from a minimum at the triple point temperature to a maximum at the critical temperature, the critical pressure. This section briefly reviews methods for both correlating vapor pressure data and for predicting vapor pressure of pure compounds. Except at very high total pressures (above about 10 MPa), there is no effect of total pressure on vapor pressure. If such an effect is present, a correction, the Poynting correction, can be applied. The pressure exerted above a solid-vapor mixture may also be called vapor pressure but is normally only available as experimental data for common compounds that sublime.

Correlation Methods Vapor pressure is correlated as a function of temperature by numerous methods mainly derived from the Clapeyron equation discussed in the section on enthalpy of vaporization. The classic simple equation used for correlation of low to moderate vapor pressures is the Antoine[4] equation (2-27).

$$\ln P^{sat} = A + \frac{B}{T+C} \tag{2-27}$$

A, B, and C are regression constants for the specific compound.

The Antoine equation does not fit data accurately much above the normal boiling point. Thus, as regression by computer is now standard, more accurate expressions applicable to the critical point have become usable. The entire DIPPR Compilation[24] is regressed with the modified Riedel[89] equation (2-28) with constants available for over 1500 compounds.

$$\ln P^{sat} = A + \frac{B}{T} + C\ln T + DT^E \tag{2-28}$$

A, B, C, and D are regression constants and E is an exponent equal to 1, 2, or 6 depending on which regression gives the most accurate fit of the data.

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

For purposes of the *API Technical Data Book* (Daubert and Danner[23]), another modified Riedel equation (2-29) was chosen and found to fit hydrocarbon data well over the entire pressure range. Coefficients are given for several hundred hydrocarbons.

$$\ln P^{sat} = A + \frac{B}{T} + C \ln T + DT^2 + \frac{E}{T^2} \qquad (2\text{-}29)$$

Both equations (2-28) and (2-29) are also extrapolatable above the critical temperature where necessary for thermodynamic calculations.

The other modern equation used for correlation is the modified and linearized Wagner[124] equation (2-30), which has the advantage that it will match critical data exactly, although it cannot be extrapolated above the critical point. The equation is also included with coefficients to several hundred compounds in the *Technical Data Book—Petroleum Refining*.

$$\ln P_r = aX_1 + bX_2 + cX_3 + dX_4 \qquad (2\text{-}30)$$

where $X_1 = \dfrac{1 - T_r}{T_r}$, $X_2 = \dfrac{(1 - T_r)^{1.5}}{T_r}$, $X_3 = \dfrac{(1 - T_r)^{2.6}}{T_r}$, $X_4 = \dfrac{(1 - T_r)^5}{T_r}$

$$P_r = P^{sat}/P_c \qquad T_r = T^{sat}/T_c$$

Both Riedel and Wagner regressions usually fit data within a few tenths of a percent over the entire range between the triple point and the critical point.

Prediction Methods Two methods have gained almost universal acceptance for prediction of the vapor pressure of **pure hydrocarbons.**

The method of Lee and Kesler[55] is the preferred method if the critical temperature and the critical pressure of the hydrocarbon is known or can be reasonably predicted by the methods of the first section. The corresponding states method is shown in equation (2-31) with the simple fluid and correction terms to be calculated from equations (2-32) and (2-33), respectively, for any T_r.

$$\ln P_r^{sat} = (\ln P_r^{sat})^{(0)} + \omega(\ln P_r^{sat})^{(1)} \qquad (2\text{-}31)$$

$$(\ln P_r^{sat})^{(0)} = 5.92714 - 6.09648/T_r - 1.28862 \ln T_r + 0.169347T_r^6 \qquad (2\text{-}32)$$

$$(\ln P_r^{sat})^{(1)} = 15.2518 - 15.6875/T_r - 13.4721 \ln T_r + 0.43577T_r^6 \qquad (2\text{-}33)$$

The method is applicable at reduced temperatures above 0.30 or the freezing point, whichever is higher, and below the critical point. The method is most reliable when $0.5 < T_r < 0.95$, where errors in prediction average 3.5 percent when experimental critical properties are known. Errors are higher for predicted criticals. The method is useful when solved iteratively with Eq. (2-23) to predict the acentric factor.

Example 5 Estimate the vapor pressure of 1-butene at 98°C. Use Eq. (2-31):

$$\ln P_r^{sat} = (\ln P_r^{sat})^{(0)} + \omega(\ln P_r^{sat})^{(1)}$$

Pure component properties of 1-butene are $T_c = 146.4$°C, $P_c = 4.02$ MPa, and $\omega = 0.1867$.

$$T_r = \frac{371.1}{419.5} = 0.885$$

From Eq. (2-32): $(\ln P_r^{sat})^{(0)} = -0.7227$

From Eq. (2-33): $(\ln P_r^{sat})^{(1)} = -0.6190$

$$\ln P_r^{sat} = -.7227 + (.1867)(-0.6190)$$

$$\ln P_r^{sat} = -0.8383$$

$$P_r^{sat} = 0.4325$$

$$P^{sat} = P_r^{sat}P_c = (.4325)(4.02) = 1.74 \text{ MPa}$$

An experimental value is 1.72 MPa.

When criticals cannot be estimated with reasonable accuracy, the method of Maxwell and Bonnell[67] is recommended. The normal boiling point and the specific gravity at 60°F (15.5°C) are required inputs. According to what vapor pressure range is expected, the vapor pressure is calculated from Eqs. (2-34), (2-35), or (2-36). If the wrong range is selected, the procedure will need to be repeated.

For $X > 0.0022$ ($P^{sat} < 2$ mm Hg):

$$\log P^{sat} = \frac{3000.538X - 6.761560}{43X - 0.987672} \qquad (2\text{-}34)$$

For $0.0013 \le X \le 0.0022$ (2 mm Hg $\le P^{sat} \le$ 760 mm Hg):

$$\log P^{sat} = \frac{2663.129X - 5.994296}{95.76X - 0.972546} \qquad (2\text{-}35)$$

For $X < 0.0013$ ($P^{sat} > 760$ mm Hg):

$$\log P^{sat} = \frac{2770.085X - 6.412631}{36X - 0.989679} \qquad (2\text{-}36)$$

X is calculated from Eq. (2-37) and T'_b is calculated from Eq. (2-38). Iterative calculation may be required.

$$X = \frac{\dfrac{T'_b}{T} - 0.0002867(T'_b)}{748.1 - 0.2145(T'_b)} \qquad (2\text{-}37)$$

$$T_b - T'_b = 2.5f(K - 12) \log \frac{P^{sat}}{760} \qquad (2\text{-}38)$$

where T_b = normal boiling point, °R
T'_b = normal boiling point corrected to $K = 12$, °R
T = absolute temperature, °R
f = correction factor. For all subatmospheric vapor pressures and for all substances having normal boiling points greater than 400°F, $f = 1$. For substances having normal boiling points less than 200°F, $f = 0$. For superatmospheric vapor pressures of substances having normal boiling points between 200°F and 400°F, f is given by $(T_b - 659.7)/200$
K = Watson characterization factor, $T_b^{1/3}$/sp gr

Evaluation of the method for pure hydrocarbons shows errors averaging 8 percent for vapor pressures above 1 mm Hg and 30 percent below 1 mm Hg. The method is also usable for narrow boiling (range up to 50°F) **undefined hydrocarbon mixtures** with the only change being that the mean average boiling point replaces the normal boiling point in all calculations.

Example 6 Estimate the vapor pressure of tetralin at 150°C (302°F). Its normal boiling point is 207.6°C (405.7°F) and its Watson characterization factor is 9.78.

Use the Maxwell-Bonnell method, Eq. (2-35).

$$\log P^{sat} = \frac{2663.129X - 5.994296}{95.76X - 0.972546}$$

At 150°C with a normal boiling point of 207.6°C, a vapor pressure between 2 and 760 mm Hg would be expected.

Assume $T'_b = T_b = 405.7$°F as a first trial. From Eq. (2-37):

$$X = \frac{(865.7/762) - 0.0002867(865.7)}{748.1 - 0.2145(865.7)}$$

$$X = 0.001579$$

$$\log P^{sat} = \frac{2663.129(0.001579) - 5.994296}{95.76(0.001579) - 0.972546} = 2.179$$

$$P^{sat} = 151.0 \text{ mm Hg}$$

Use Eq. (2-38) to calculate the correction.

$$T_b - T'_b = 2.5f(K - 12) \log \frac{P^{sat}}{760} = 2.5(1)(9.48 - 12) \log \frac{151}{760}$$

$$T_b - T'_b = 4.4°$$

Thus, for the second trial, $T'_b = 405.7 - 4.4 = 401.3$°F.

Using Eq. (2-37), recalculate X.

$$X = \frac{(861.3/762) - 0.0002867(861.3)}{748.1 - 0.2145(861.3)} = 0.001568$$

From Eq. (2-35), $\log P^{sat} = 2.214$; $P^{sat} = 163.7$ mm Hg. Use Eq. (2-38) to recalculate the correction.

$$T_b - T'_b = 2.5(1)(9.48 - 12) \log \frac{163.7}{760} = 4.2°$$

Thus, $T'_b = 401.5$°F. If greater accuracy is desired, carry out a third trial. (An experimental vapor pressure is 161.8 mm Hg.)

For **nonhydrocarbon organics,** vapor pressures above 15 kPa for com-

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

pounds of known or estimable normal boiling point are predicted using the method of Riedel[89] given by Eq. (2-39).

$$\log P_r^\circ = \phi(T_r) - (\alpha - 7)\psi(T_r) \tag{2-39}$$

Correlation functions $\phi(T_r)$, $\psi(T_r)$, and $\zeta(T_r)$ are given by Eqs. (2-40), (2-41), and (2-42), respectively.

$$\phi(T_r) = 0.118\zeta(T_r) - 7\log_{10} T_r \tag{2-40}$$

$$\psi(T_r) = 0.0364\zeta(T_r) - \log_{10} T_r \tag{2-41}$$

$$\zeta(T_r) = 36/T_r + 96.7\log_{10} T_r - 35 - T_r^6 \tag{2-42}$$

The Riedel α is calculated from Eq. (2-43).

$$\alpha = \frac{0.136\zeta(T_{r_b}) + \log_{10} P_c - 5.01}{0.0364\zeta(T_{r_b}) - \log_{10} T_{r_b}} \tag{2-43}$$

Critical properties, if not available, can be estimated from the methods of the previous section. T_r is the reduced temperature at the temperature of interest, while T_{r_b} is the reduced temperature at the normal boiling point.

The method is accurate within 2 to 3 percent above 15 kPa, while errors increase to 10–30 percent at lower pressures. Care should be taken not to use the method below the freezing point temperature.

Example 7 Estimate the vapor pressure of thiophene at 500 K. Pure component properties are $T_c = 579.4$ K, $P_c = 5.694$ MPa, and $T_b = 357.5$ K. Use the Riedel method, Eq. (2-39).

$$\log P_r^{sat} = -\phi(T_r) - (\alpha - 7)\ \psi\ (T_r)$$

$$T_{r_b} = \frac{357.5}{579.4} = 0.6170 \qquad T_r = \frac{500}{579.4} = 0.8629$$

From Eq. (2-42):

$$\zeta(T_{r_b}) = \frac{(36)}{(0.6170)} + 96.7\log(0.6170) - 35 - (0.6170)^6 = 3.01$$

From Eq. (2-43):

$$\alpha = \frac{0.136(3.01) + \log(5.694 \times 10^6) - 5.01}{(0.0364)(3.01) - \log(0.6170)}$$

$$\alpha = 6.749$$

From Eq. (2-42), calculate $\zeta(T_r)$ and then calculate $\phi(T_r)$ and $\psi(T_r)$ from Eqs. (2-40) and (2-41).

$$\log P_r^{sat} = -0.461 - (6.749 - 7)(0.068)$$

$$\log P_r^{sat} = -0.444$$

$$P_r^{sat} = 0.3598$$

$$P^{sat} = P_r^{sat} P_c = (.3598)(5.694) = 2.049 \text{ MPa}$$

An experimental value is 2.037 MPa.

For **nonhydrocarbon organics** for which normal boiling points are unknown or expected vapor pressures are below 15 kPa, the reference substance method of Othmer and Yu[78] as given by Eq. (2-44) is recommended.

$$\log P^{sat} = m \log P_w^{sat} + C \tag{2-44}$$

The vapor pressure of water P_w^{sat} may be calculated by Eq. (2-45).

$$\log P_w^{sat} = 31.51 - \frac{3.1298 \times 10^3}{T} - 7.1385\log T + 1.757 \times 10^{-6} T^2 \tag{2-45}$$

with temperatures in K and vapor pressures in Pa.

Values of the compound specific constants m and c were originally derived by Othmer et al. and greatly expanded to over 600 common organics by Danner and Daubert.[22] If constants are not available but any two vapor pressure data points are available, the constants m and C can be calculated using Eqs. (2-46) and (2-47).

$$m = \frac{\log P_1^{sat} - \log P_2^{sat}}{\log P_{w_1}^{sat} - \log P_{w_2}^{sat}} \tag{2-46}$$

$$C = \log P_1^{sat} - m \log P_{w_1}^{sat} \tag{2-47}$$

where the subscripts 1 and 2 refer to the two reference temperatures T_1 and T_2.

Average errors at low pressures for compounds with tabulated m and C are within a few percent. When values of m and C are calculated from only two vapor pressure points, the method should be used only for interpolation and limited extrapolation. The method is usable from about 220 K (so long as it is above the freezing point of the compound) to the critical point of water (about 647 K).

Example 8 Estimate the vapor pressure of acetaldehyde at 0°C. Two vapor pressure points are 20.0 kPa at 256.55 K and 107.6 kPa at 294.85 K.

Use Eq. (2-44), determining parameters from Eqs. (2-45), (2-46), and (2-47).

$$\log P^{sat} = m \log Pw^{sat} + C$$

$$\text{at } T_1 = 256.55 \text{ K},\ P_1^{sat} = 2.00 \times 10^4 \text{ Pa},\ \log P_1^{sat} = 4.3010$$

$$\text{at } T_2 = 294.95 \text{ K},\ P_2^{sat} = 1.067 \times 10^5 \text{ Pa},\ \log P_2^{sat} = 5.0282$$

Use Eq. (2-45) to calculate the vapor pressure of water at T_1 and T_2.

$$\log P_{\omega_1}^{sat} = 2.2282, \quad P_{\omega_1}^{sat} = 169.12 \text{ Pa}$$

$$\log P_{\omega_2}^{sat} = 3.4213, \quad P_{\omega_2}^{sat} = 2637.9 \text{ Pa}$$

From Eq. (2-46):

$$m = \frac{\log P_1^{sat} - \log P_2^{sat}}{\log P_{w_1}^{sat} - \log P_{w_2}^{sat}} = \frac{4.3010 - 5.0282}{2.2282 - 3.4213} = 0.6093$$

From Eq. (2-47):

$$C = \log P_1^{sat} - m \log P_{w_1}^{sat} = 4.3010 - 0.6093(2.2282)$$

$$C = 2.9434$$

at $\quad T = 273.15$ K (0°C)

$$\log P_w^{sat} = 31.51 - \frac{3129.8}{273.15} - 7.1385\log 273.15 + 1.757 \times 10^{-6}(273.15)^2$$

$$\log P_w^{sat} = 2.7907$$

$$\log P^{sat} = (0.6093)(2.7907) + 2.9434$$

$$\log P^{sat} = 4.6438$$

$$P^{sat} = 44{,}030 \text{ Pa} = 44.0 \text{ kPa}$$

IDEAL GAS THERMAL PROPERTIES

A substance is in the ideal gas state when the volume of its molecules is a zero fraction of the total volume taken up by the substance and when the individual molecules are far enough apart from each other so that there is no interaction between them. Although this only occurs at infinite volume and zero pressure, in practice, ideal gas properties can be used for gases up to a pressure of two atmospheres with little loss of accuracy. Thermal properties of ideal gas mixtures may be obtained by mole-fraction averaging the pure component values.

Heat Capacity, C_p^o Heat capacity is defined as the amount of energy required to change the temperature of a unit mass or mole one degree; typical units are J/kg·K or J/kmol·K. There are many sources of ideal gas heat capacities in the literature; e.g., Daubert et al.,[24] Daubert and Danner,[23] JANAF thermochemical tables,[15] TRC thermodynamic tables,[115,116] and Stull et al.[104] If C_p^o values are not in the preceding sources, there are several estimation techniques that require only the molecular structure. The methods of Thinh et al.[113] and Benson et al.[6,7] are the most accurate but are also somewhat complicated to use. The equation of Harrison and Seaton[36] for C_p^o between 300 and 1500 K is almost as accurate and easy to use:

$$C_p^o = a_1 + a_2\text{C} + a_3\text{H} + a_4\text{O} + a_5\text{N} + a_6\text{S} + a_7\text{F} + a_8\text{Cl} + a_9\text{I} + a_{10}\text{Br} + a_{11}\text{Si} + a_{12}\text{Al} + a_{13}\text{B} + a_{14}\text{P} + a_{15}\text{E} \tag{2-48}$$

where
- C_p^o = ideal gas heat capacity, J/mol K
- a_1–a_{15} = constant parameters obtained from Table 2-387 as a function of temperature
- C = number of carbon atoms in the molecule
- H = number of hydrogen atoms in the molecule
- O = number of oxygen atoms in the molecule
- N = number of nitrogen atoms in the molecule
- S = number of sulfur atoms in the molecule
- F = number of fluorine atoms in the molecule
- Cl = number of chlorine atoms in the molecule
- I = number of iodine atoms in the molecule
- Br = number of bromine atoms in the molecule
- Si = number of silicon atoms in the molecule
- Al = number of aluminum atoms in the molecule
- B = number of boron atoms in the molecule
- P = number of phosphorus atoms in the molecule
- E = number of atoms in the molecule excluding the 13 atom-types listed above

TABLE 2-387 Values of the Constant Parameters a_1–a_{15} in Eq. (2-48) at Different Temperatures

	Parameter a														
Temp., K	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
300	4.86	9.04	5.69	11.4	11.9	15.3	12.7	16.8	18.7	17.8	14.6	15.8	11.5	18.0	19.5
400	0.864	12.6	7.37	13.9	14.0	17.0	16.2	18.9	20.5	19.9	17.5	18.3	14.7	20.9	20.8
500	−1.85	15.5	8.89	15.7	16.0	19.4	17.9	20.2	22.1	21.2	19.6	20.0	17.0	21.6	21.7
600	−4.61	17.5	10.5	17.5	17.3	20.3	20.1	21.4	23.3	22.4	20.9	21.1	18.3	22.8	22.1
800	−7.49	20.1	13.1	19.4	19.4	22.3	21.5	22.4	25.0	23.4	23.2	22.3	20.8	23.0	23.0
1000	−8.53	21.6	15.2	20.4	20.4	22.9	22.4	22.8	25.4	23.8	23.9	22.8	22.2	23.4	23.3
1500	−7.37	23.9	17.9	20.6	21.1	22.5	22.1	22.6	24.6	23.0	24.1	23.2	24.2	24.2	23.3

Results and parameters may be interpolated between temperatures. Average errors are between 2 and 6 percent, with the higher errors at the lower temperatures.

Example 9 Using Eq. 2-48 to estimate the ideal gas heat capacity of acetone (C_3H_6O) at 600 K:

$$C_p^\circ = -4.61 + (17.5)(3) + (10.5)(6) + (17.5)(1) = 128.39 \text{ J/mol K}$$

Daubert et al.[24] report a value of 121.8 J/mol K.

Enthalpy of Formation The ideal gas standard enthalpy (heat) of formation (ΔH°_{f298}) of a chemical compound is the increment of enthalpy associated with the reaction of forming that compound in the ideal gas state from the constituent elements in their standard states, defined as the existing phase at a temperature of 298.15 K and one atmosphere (101.3 kPa). Sources for data are Refs. 15, 23, 24, 104, 115, and 116. The most accurate, but again complicated, estimation method is that of Benson et al.[6,7] A compromise between complexity and accuracy is based on the additive atomic group-contribution scheme of Joback[44]; his original units of kcal/mol have been converted to kJ/mol by the conversion 1 kcal/mol = 4.1868 kJ/mol:

$$\Delta H^\circ_{f298} = 68.29 + \sum_{i=1}^{n} N_i \, \Delta_{Hi} \qquad (2\text{-}49)$$

where ΔH°_{f298} = enthalpy of formation at 298.15 K, kJ/mol
n = number of different atomic groups contained in the molecule
N_i = number of atomic groups i contained in the molecule
Δ_{Hi} = numeric value of atomic group i obtained from Table 2-388.

Average expected errors are about 9 kJ/mol.
For **other temperatures:**

$$\Delta H^\circ_{fT} = \Delta H^\circ_{f298} + \int_{298}^{T} C_p^\circ \, dT \qquad (2\text{-}50)$$

See above for discussion of the ideal gas heat capacity (C_p°).

Example 10 The ΔH°_{f298} of 2-butanol is estimated using Table 2-388. The molecular groups are $2CH_3$, $1CH_2$, 1CH (all nonring), and 1OH (alcohol). Therefore:

$$\Delta H^\circ_{f298} = 68.29 + 2(-76.45) + (-20.64) + (29.89) + (-208.04) = -283.40 \text{ kJ/mol}$$

The value from Daubert et al.[24] is −292.9 kJ/mol.

Gibbs Energy of Formation The ideal gas standard Gibbs energy of formation (ΔG°_{f298}) of a chemical compound is the increment of Gibbs energy associated with the reaction of forming that compound in the ideal gas state from the constituent elements in their standard state defined as the existing phase at a temperature of 298.15 K and one atmosphere (101.325 kPa). Refs. 15, 23, 24, 104, 115, and 116 are good sources of data. The additive atomic group-contribution scheme of Joback[44] may be used to estimate ΔG°_{f298}; his original units of kcal/mol have been converted to kJ/mol by the conversion 1 kcal/mol = 4.1868 kJ/mol:

$$\Delta G^\circ_{f298} = 53.88 + \sum_{i=1}^{n} N_i \, \Delta_{Gi} \qquad (2\text{-}51)$$

where ΔG°_{f298} = Gibbs energy of formation at 298.15 K, kJ/mol
n = number of different atomic groups contained in the molecule
N_i = number of atomic groups i contained in the molecule
Δ_{Gi} = numeric value of atomic group i obtained from Table 2-388

Average errors of 8 to 9 kJ/mol may be expected.

Example 11 The ΔG°_{f298} of phenol is estimated using Table 2-388. The molecular groups are

5 ═CH (with one single bond up)

1 ═C— (with one single bond up) (both ring)

1 OH (phenol)

Therefore,

$$\Delta G^\circ_{f298} = 53.88 + 5(11.30) + (54.05) + (-197.37) = -32.94 \text{ kJ/mol}$$

The value from Daubert et al.[24] is −32.64 kJ/mol.

For **other temperatures,** the exact Eq. (2-52) may be used at temperature T (K):

$$\Delta G^\circ_{fT} = \Delta H^\circ_{fT} - T\,\Delta S^\circ_{fT} \qquad (2\text{-}52)$$

where ΔG°_{fT} = Gibbs energy of formation at T, kJ/mol
ΔH°_{fT} = enthalpy of formation at T, kJ/mol (see above)
ΔS°_{fT} = entropy of formation at T, kJ/mol K (see below)

Entropy of Formation The ideal gas standard entropy of formation (ΔS°_{f298}) of a chemical compound is the increment of entropy associated with the reaction of forming that compound in the ideal gas state from the constituent elements in their standard state defined as the existing phase at a temperature of 298.15 K and one atmosphere (101.325 kPa). Thus:

$$\Delta S^\circ_{f298} = S^\circ_{\text{compound}} - \sum_{i=1}^{n} N_i S^r_{\text{element } i} \qquad (2\text{-}53)$$

where ΔS°_{f298} = entropy of formation at 298.15 K and 1 atm, J/mol K
$S^\circ_{\text{compound}}$ = ideal gas absolute entropy of the compound at 298.15 K and 1 atm, J/mol K
n = number of different elements contained in the compound
N_i = moles of element i contained in one mole of compound
$S^r_{\text{element } i}$ = absolute entropy of element i in its standard state at 298.15 K and 1 atm, J/mol K.

Ideal gas absolute entropies of many compounds may be found in Daubert et al.,[24] Daubert and Danner,[23] JANAF Thermochemical Tables,[15] TRC Thermodynamic Tables,[115,116] and Stull et al.[104] Otherwise, the estimation method of Benson et al.[6,7] is reasonably accurate, with average errors of 1–2 J/mol K. Elemental standard-state absolute entropies may be found in Cox et al.[21] Values from this source for some common elements are listed in Table 2-389. ΔS°_{f298} may also be calculated from Eq. (2-52) if values for ΔH°_{f298} and ΔG°_{f298} are known.

ENTHALPY OF VAPORIZATION AND FUSION

Enthalpy of Vaporization The enthalpy (heat) of vaporization ΔH_V is defined as the difference of the enthalpies of a unit mole or mass of a saturated vapor and saturated liquid of a pure component; i.e., at a temperature (below the critical temperature) and corresponding vapor pressure. ΔH_V is related to vapor pressure by the thermodynamically exact Clausius-Clapeyron equation:

$$\Delta H_v = -R\,\Delta Z_V \frac{d \ln P^{sat}}{d\,(1/T)} \tag{2-54}$$

where R = gas constant in energy units

$$\Delta Z_V = Z_G - Z_L \tag{2-55}$$

Z_G = compressibility factor of the saturated vapor
Z_L = compressibility factor of the saturated liquid
P^{sat} = vapor pressure
T = absolute temperature

If accurate Z_G and Z_L data are available, excellent ΔH_V values can be obtained by differentiating a vapor pressure correlation and using Eq. (2-54). If not, ΔZ_V may be esimated by Haggenmacher's equation[34]:

TABLE 2-389 Standard-State Entropy of Elements at 298.15 K and 1 Atmosphere

Element	State	Absolute entropy J/mol K
C	crystal (graphite)	5.74
H_2	gas	130.571
O_2	gas	205.043
N_2	gas	191.500
S	crystal (rhombic)	32.054
F_2	gas	202.682
Cl_2	gas	222.972
Br_2	liquid	152.21
I_2	crystal	116.14

$$\Delta Z_v = \left(1 - \frac{P_r}{T_{r^3}}\right)^{1/2} \tag{2-56}$$

where P_r = reduced pressure = P/P_c
T_r = reduced temperature = T/T_c

However, Eq. (2-56) should be used only near or below the normal boiling point; even then, the accuracy of the resulting ΔH_V is significantly reduced.

The corresponding states approach suggested by Pitzer et al.[82] requires only the critical temperature and acentric factor of the compound. For a close approximation, an analytical representation of this method proposed by Reid et al.[86] for $0.6 < T_r < 1.0$ is:

$$\Delta H_V/RT_c = 7.08(1 - T_r)^{0.354} + 10.95\omega(1 - T_r)^{0.456} \tag{2-57}$$

where ΔH_V = enthalpy of vaporization, kJ/mol
R = gas constant = 0.008314 kJ/mol K
T_c = critical temperature, K
T_r = reduced temperature, T/T_c
T = temperature, K
ω = acentric factor

Maximum errors are in the order of 8 percent.

Example 12 Estimate ΔH_V of Propionaldehyde at 350 K. The required properties from Daubert et al.[24] are T_c = 504.4 K and ω = 0.2559. T_r = 350.0/504.4 = 0.6939. Substituting in Eq. (2-57):

$$\Delta H_V/RT_c = (7.08)(1 - 0.6939)^{0.354} + (10.95)(0.2559)(1 - 0.6939)^{0.456} = 6.289$$

$$\Delta H_V = (6.289)(0.008314)(504.4) = 26.37 \text{ kJ/mol}$$

The reported value is 26.85 kJ/mol.[24]

The enthalpy of vaporization **at the normal boiling temperature** ΔH_{vb} (kJ/mol) can be estimated by an equation suggested by Riedel[90]:

$$\Delta H_{vb} = 1.093\, RT_c \left[T_{br} \frac{(\ln [P_c/101.325] - 1)}{0.930 - T_{br}} \right] \tag{2-58}$$

where R = gas constant = 0.008314 kJ/mol K.
T_c = critical temperature, K
T_{br} = reduced normal boiling temperature = T_b/T_r
T_b = normal boiling temperature, K
P_c = critical pressure, kPa

Average errors are about 2 percent.

Example 13 Estimate ΔH_{Vb} of Ethyl Acetate. The required properties for ethyl acetate are from Daubert et al.[24]: T_c = 523.3 K, T_b = 350.2 K, and P_c = 3880.0 kPa. T_{br} = 350.2/523.3 = 0.6692. Substituting in Eq. (2-58):

$$\Delta H_{Vb} = (1.093)(0.008314)(523.3) \left[(0.6692) \left(\frac{(\ln [3880.0/101.325] - 1)}{0.930 - 0.6692} \right) \right]$$

$$= 32.28 \text{ kJ/mol}$$

The value from Daubert et al.[24] is 32.23 kJ/mol.

The enthalpy of vaporization decreases with temperature and is zero at the critical point. If the value of an enthalpy of vaporization ΔH_{v_1} is known at temperature T_1, this temperature dependency can be represented by the Watson relation[127] to calculate another enthalpy of vaporization ΔH_{v_2} at any other temperature T_2:

$$\Delta H_{v_2} = \Delta H_{v_1} \left(\frac{1 - T_{r_2}}{1 - T_{r_1}} \right)^{0.38} \tag{2-59}$$

where $T_{r_{1,2}}$ = reduced temperature = T_1/T_c or T_2/T_c
$T_{1,2}$ = temperature, K
T_c = critical temperature, K

Equation (2-59) works best between the normal boiling and critical temperatures, producing values of engineering accuracy.

Example 14 Estimate ΔH_v of ethyl acetate at 450 K, using the normal boiling point values as a basis (see Example 13). ΔH_{v_1} = 32.23 kJ/mol, T_{r_1} = 0.6692, and T_{r_2} = 450.0/523.3 = 0.8599. Substituting in Eq. (2-59):

$$\Delta H_{v(450)} = 32.23 \left(\frac{1 - 0.8599}{1 - 0.6692} \right)^{0.38} = 23.25 \text{ kJ/mol}$$

A value of 23.16 kJ/mol is obtained from Daubert et al.[24]

Enthalpy of Fusion The enthalpy (heat) of fusion ΔH_{fus} is defined as the difference of the enthalpies of a unit mole or mass of a solid and liquid at its melting temperature and one atmosphere pressure of a pure component. There are no generally applicable estimation techniques that are very accurate. However, if the melting temperature is known, the atomic group contribution method of Chickos et al.[16] yields approximate results:

$$\Delta H_{fus} = T_{mlt} \Delta S_{fus} \tag{2-60}$$

where ΔH_{fus} = enthalpy of fusion at the melting temperature, J/mol
T_{mlt} = melting temperature, K
ΔS_{fus} = $a + b$ = entropy of fusion at the melting temperature, J/mol K.

It should be noted that the methodology for a and b results in a ΔS_{fus} associated with the phase change from a solid at 0 K to the liquid at T_{mlt}. No entropy changes resulting from solid transitions are taken into account, and ΔS_{fus} for a substance that undergoes such a transition will be overestimated by this technique.

$$a = 35.19\, N_R + 4.289\, (N_{CH_2} - 3\, N_R) \tag{2-61}$$

where N_R = number of nonaromatic rings
N_{CH_2} = number of —CH_2— atomic groups in nonaromatic ring(s) required to form a cyclic paraffin of the same ring size(s) as contained in the molecule of interest.

Example: For  , N_{CH_2} = 5; a = 0 if there are no nonaromatic rings in the molecule of interest. If a nonaromatic ring in fact contains a —CH_2— atomic group, then no consideration of that group in the b term in Eq. (2-62) is required.

$$b = \sum_{i=1}^{n_g} (N_g)_i(\Delta_s)_i + \sum_{j=1}^{n_s} (N_s)_j(C_s)_j(\Delta_s)_j + \sum_{k=1}^{n_f} (N_f)_k(C_t)_k(\Delta_s)_k \tag{2-62}$$

where n_g = number of different nonring or aromatic C-H atomic groups bonded to other carbon atoms in the molecule of interest
$(N_g)_i$ = number of C-H atomic groups i bonded to other carbon atoms in the molecule of interest
n_s = number of different nonring or aromatic C-H atomic groups bonded to at least one functional group or atom in the molecule of interest
$(N_s)_j$ = number of C-H atomic groups j bonded to at least one functional group or atom in the molecule of interest
n_f = number of different functional groups or atoms in the molecule of interest
$(N_f)_k$ = number of functional groups or atoms k in the molecule of interest
$(C_s)_j$ = coefficient for C-H atomic group j bonded to at least one functional group or atom in the molecule of interest; numeric values for C-H atomic groups are found in Table 2-390
C_t = coefficient for the functional group or atom k in the molecule of interest, where t = the total number of functional groups or atoms in the molecule of interest. *Exception:* Molecules containing any number of fluorine atoms are treated as having only one functional fluorine atom. Numeric values of C_1–C_4 are in Table 2-391 for functional groups or atoms
$(\Delta_s)_{i,j,k}$ = contribution of the atomic group or atom i, j, or k to the entropy of fusion, J/mol K. Numeric values for C-H atomic groups are in Table 2-390; values for functional groups or atoms are in Table 2-391

TABLE 2-390 C_s and Δ_s Values for C-H Atomic Groups to Estimate ΔH_{fus}

	C_s	Δ_s
Nonring		
$-CH_3$	1.0	18.33
$-CH_2-$	1.0	9.41
$-CH<$ (—CH with two further single bonds)	0.69	−16.19
$>C<$ (—C— with two further single bonds)	0.67	−38.70
$=CH_2$	1.0	14.56
$=CH-$	3.23	4.85
$=C<$	1.0	−11.38
$\equiv CH$	1.0	10.88
$\equiv C-$	1.0	2.18
Aromatic		
CH (aromatic)	1.0	6.44
C— (bonded to paraffinic C)	1.0	−10.33
C— (bonded to olefinic C or non-C)	1.0	−4.27
C— (bonded to acetylenic C)	1.0	−2.51
Ring		
$>CH-$	0.76	−15.98
$>C<$	1.0	−32.97
$=CH-$ (ring)	0.62	−4.35
$=C<$ (ring)	0.86	−11.72
$\equiv C-$ or $=C=$	1.0	−5.36

Chickos et al.[16] report an average error of 2050 J/mol for monofunctional molecules and 3180 J/mol for multifunctional molecules when using their method to estimate ΔH_{fus}. Four **example** estimations are shown in Table 2-392.

SOLID AND LIQUID HEAT CAPACITY

The heat capacity is defined as the amount of energy required to change the temperature of a unit mass or mole one degree; typical units are J/kg·K or J/kmol·K.

Solid Heat Capacity Solid heat capacity increases with increasing temperature, with steep rises near the triple point for many compounds. When experimental data are available, a simple polynomial equation in temperature is often used to correlate the data. It should be noted that step changes in heat capacity occur if the compound undergoes crystalline state changes at different temperatures.

There are no reliable prediction methods for solid heat capacity as a function of temperature. However, the atomic element contribution method of Hurst and Harrison,[41] which is a modification of Kopp's Rule,[50] provides estimations at 298.15 K and is easy to use:

$$C_{pS} = \sum_{i=1}^{n} N_i \Delta_{Ei} \qquad (2\text{-}63)$$

where C_{pS} = solid heat capacity at 298.15 K, J/mol K
n = number of different atomic elements in the compound
N_i = number of atomic elements i in the compound
Δ_{Ei} = numeric value of the contribution of atomic element i found in Table 2-393

Average errors are in the 9–10 percent range.

Example 15 Estimate solid heat capacity of dibenzothiophene, $C_{12}H_8S$. The required atomic element contributions from Table 2-393 are: C = 10.89, H = 7.56, and S = 12.36. Substituting in Eq. (2-63):

$$C_{pS} = (12)(10.89) + (8)(7.56) + (1)(12.36) = 203.52 \text{ J/mol K}$$

Daubert et al.[24] report a value of 198.5 J/mol K.

Liquid Heat Capacity The two commonly used liquid heat capacities are either at constant pressure or at saturated conditions. There is negligible difference between them for most compounds up to a reduced temperature (temperature/critical temperature) of 0.7. Liquid heat capacity increases with increasing temperature, although a minimum occurs near the triple point for many compounds.

There are a number of reliable estimating techniques for obtaining **pure-component** liquid heat capacity as a function of temperature, including Ruzicka and Dolmalski,[93,94] Tarakad and Danner,[112] and Lee and Kesler.[55] These methods are somewhat complicated. The relatively simple atomic group contribution approach of Chueh and Swanson[17] for liquid heat capacity **at 293.15 K** is presented here:

$$C_{pL} = \sum_{i=1}^{n} N_i \Delta_{cpi} + 18.83m \qquad (2\text{-}64)$$

where C_{pL} = liquid heat capacity at 293.15 K, J/mol K.
n = number of different atomic groups in the compound
N_i = number of atomic groups i in the compound
Δ_{cpi} = numeric value of the contribution of atomic element i found in Table 2-394. The original units of cal/mol K have been converted to J/mol K by the conversion 1 cal/mol K = 4.184 J/mol K
m = number of carbon groups requiring an additional contribution, which are those that are joined by a single bond to a carbon group, which in turn is connected to a third carbon group by a double or triple bond. If a carbon group meets this criterion in more than one way, m should be increased by one for each of the ways. *Exceptions:* $-CH_3$ groups or carbon groups in a ring never require an additional contribution; and the *first* additional contribution for a $-CH_2-$ group is 10.46 J/mol K rather than 18.83 J/mol K. However, if the $-CH_2-$ group meets the criterion in a second way, the *second* additional contribution reverts to the 18.83 J/mol K value (see Example 17, below).

Errors should be less than 6 percent for all compounds except for acids, amines, and halides.

Example 16 Estimate the liquid heat capacity at 293.15 K of 2-butanol. The atomic groups are:

2 $-CH_3$

1 $-CH_2-$

1 $-CHOH$

Substituting in Eq. (2-64) the atomic group contributions from Table 2-394 with $m = 0$:

$$C_{pL} = (2)(36.82) + (1)(30.38) + (1)(76.15) = 180.17 \text{ J/mol K}$$

The value from Daubert et al.[24] is 190.3 J/mol K.

I	25.29	Li	23.25	W	30.87
Al	18.07	Mg	22.69	Zr	26.82
B	10.10	Mn	28.06	All other	26.63

Example 17 Estimate liquid heat capacity at 293.15 K of 1,4-pentadiene, $CH_2{=}CH{-}CH_2{-}CH{=}CH_2$. The atomic groups are:

$$2 \quad {=}CH_2$$

$$2 \quad {=}\overset{|}{C}H$$

$$1 \quad {-}CH_2{-}$$

The $-CH_2-$ group is twice joined by a single bond to a carbon group, which in turn is connected to a third carbon group by a double bond, and $m = 2$. However, by the second exception, the first additional contribution is 10.46 J/mol K rather than 18.83 J/mol K. Substituting in Eq. (2-64) the atomic group contributions from Table 2-394:

$$C_{pL} = (2)(21.76) + (2)(21.34) + (1)(30.38) + 10.46 + 18.83 = 145.87 \text{ J/mol K}$$

Daubert et al.[24] report a value of 145.6 J/mol K.

For **liquid mixtures,** the values of the pure components can be mole-fraction-averaged. This procedure neglects any heat of mixing effects.

DENSITY

Density is defined as the mass of a substance contained in a unit volume. In the SI system of units, the ratio of the density of a substance to the density of water at 15°C is known as its relative density, while the older term *specific gravity* is the ratio relative to water at 60°F. Various units of density, such as kg/m^3, lb-mass/ft^3, and g/cm^3, are commonly used. In addition, molar densities, or the density divided by the molecular weight, is often specified. This section briefly discusses methods of correlation of density as a function of temperature and presents the most common accurate methods for prediction of vapor, liquid, and solid density.

Correlation Methods Vapor densities are not correlated as functions of temperature alone, as pressure and temperature are both important. At high temperatures and very low pressures, the ideal gas law can be applied; while at moderate temperature and low pressure, vapor density is usually correlated by the virial equation. Both methods will be discussed later.

Molar liquid density (ρ) is best correlated by an equation adopted from the Rackett predictor. The equation has the form of Eq. (2-65):

$$\rho = \frac{A}{B^{\left(1-\frac{T}{C}\right)^D}} \tag{2-65}$$

The regression constants A, B, and D are determined from the nonlinear regression of available data, while C is usually taken as the critical temperature. The liquid density decreases approximately linearly from the triple point to the normal boiling point and then nonlinearly to the critical density (the reciprocal of the critical volume). A few compounds such as water cannot be fit with this equation over the entire range of temperature. Liquid density data to be regressed should be at atmospheric pressure up to the normal boiling point, above which saturated liquid data should be used. Constants for 1500 compounds are given in the DIPPR compilation.[24]

Solid density data are sparse and usually only available over a narrow temperature range, for which the general decrease in density with temperature is approximately linear.

Vapor Density Prediction A myriad of methods exist for prediction of vapor density as a function of temperature and pressure. This section will only present the most accurate and generally used methods.

For simple molecules at temperatures above the critical and at pressures no more than a few atmospheres, the ideal gas law, Eq. (2-66), may be used to estimate vapor density.

$$\rho = \frac{1}{V} = \frac{P}{RT} \tag{2-66}$$

At slightly higher pressures up to a reduced pressure of about 0.4, the truncated virial equation, Eq. (2-67), is commonly used for all types of organic fluids.

$$Z = \frac{PV}{RT} = 1 + \frac{B}{V} \tag{2-67a}$$

$$Z = \frac{P}{\rho RT} = 1 + B\rho \tag{2-67b}$$

Second virial coefficients, B, are a function of temperature and are available for about 1500 compounds in the DIPPR compilation.[24] The second virial coefficient can be regressed from experimental PVT data or can be reasonably and accurately predicted. Tsonopoulos[117] proposed a prediction method for nonpolar compounds that requires the critical temperature, critical pressure, and acentric factor. Equations (2-68) through (2-70) describe the method.

$$\frac{BP_c}{RT_c} = B_0 + \omega B_1 \tag{2-68}$$

$$B_0 = 0.1445 - \left(\frac{0.330}{T_r}\right) - \left(\frac{0.1385}{T_r^2}\right) - \left(\frac{0.0121}{T_r^3}\right) - \left(\frac{0.000607}{T_r^5}\right) \tag{2-69}$$

$$B_1 = 0.0637 + \left(\frac{0.0331}{T_r^2}\right) - \left(\frac{0.423}{T_r^3}\right) - \left(\frac{0.008}{T_r^8}\right) \tag{2-70}$$

For non-hydrogen-bonding polar compounds such as carbonyls and ethers, Tsonopoulos[117] recommends that Eq. (2-68) be expanded to a third term that is a function of the reduced dipole moment (μ_r) as described by Eqs. (2-71) through (2-73):

$$\frac{BP_c}{RT_c} = B_0 + \omega B_1 + B_2 \tag{2-71}$$

$$B_2 = -0.0002410\lambda_r - 4.308 \times 10^{-21}\lambda_r^8 \tag{2-72}$$

$$\lambda_r = \frac{10^5\lambda_p^2 P_c}{T_c^2} \tag{2-73}$$

The dipole moment λ_p in Eq. (2-73) is in debyes, while P_c is in atm and T_c is in K. Units must be watched carefully. For hydrogen-bonding molecules, Eq. (2-71) can be used with a value of B_2 calculated by Eq. (2-74).

$$B_2 = \frac{a}{T_r^6} - \frac{b}{T_r^8} \tag{2-74}$$

Variables a and b are specific constants reported by Tsonopoulos[117] for some alcohols and water (e.g., methanol: $a = 0.0878$, $b = 0.0560$; and water: $a = 0.0279$, $b = 0.0229$). Tsonopoulos also gives specific prediction methods for haloalkanes[118] and water pollutants.[119]

Example 18 Estimate the molar volume of isobutane at 155°C and 1.0 MPa pressure. Properties of isobutane are $T_c = 135.0$°C, $P_c = 3.647$ MPa, and $\omega = 0.1170$.

$$T_r = \frac{155 + 273.1}{135 + 273.1} = 1.05 \qquad P_r = \frac{1.0}{3.647} = 0.274$$

Since reduced pressure is below 0.4, use virial equation (2-67*a*). Calculate B by the Tsonopoulos method, Eq. (2-68).

$$\frac{BP_c}{RT_c} = B_0 + \omega B_1$$

Using Eq. (2-69):

$$B_0 = 0.1445 - \left(\frac{0.330}{1.05}\right) - \left(\frac{0.1385}{1.05^2}\right) - \left(\frac{0.0121}{1.05^3}\right) - \left(\frac{0.000607}{1.05^5}\right)$$

$$B_0 = 0.1445 - 0.3143 - 0.1256 - 0.0105 - 0.0005 = -0.3064$$

Using Eq. (2-70):

$$B_1 = 0.0637 + \left(\frac{0.0331}{1.05^2}\right) - \left(\frac{0.423}{1.05^3}\right) - \left(\frac{0.008}{1.05^8}\right)$$

$$B_1 = 0.0637 + 0.0300 - 0.3654 - 0.0054 = -0.2771$$

$$B = \frac{[-0.3064 + (0.1770)(-0.2771)](8314)(408.1)}{(3.647 \times 10^6)} = -0.3307$$

$$\frac{PV}{RT} = 1 + \frac{B}{V}$$

$$\frac{10^6 V}{(8314)(428.1)} = 1 - \frac{0.3307}{V}$$

Trial and error or the quadratic formula can be used for the solution. If you opt for trial and error, start with the ideal gas value ($B = 0$) where $V = 3.559$ m^3/kmole [Eq. (2-66)].

Solving, $V = 3.190$ m^3/kmole.

For prediction of vapor density of **pure hydrocarbon and nonpolar gases,** the corresponding states method of Pitzer et al.[82] is the most accurate method, with errors of less than 1 percent except in the critical region where errors of up to 30 percent can occur. The method correlates the compressibility factor by Eq. (2-75), after which the density can be calculated by Eq. (2-75):

$$Z = Z^{(0)} + \omega Z^{(1)} \tag{2-75}$$

$$\rho = \frac{P}{ZRT} = \frac{1}{V} \tag{2-76}$$

$Z^{(0)}$ is the compressibility factor for the simple fluid, while $Z^{(1)}$ is the correction term for molecular acentricity, both of which are functions of T_r and P_r. Both

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

plots and detailed tabulations of the functions are available in the *Technical Data Book*.[23] Critical temperature and pressure and the acentric factor from tabulations or as predicted are required. For hydrogen, T_c and P_c should be taken as 41.7 K and 2100 kPa, respectively. For approximate calculations, Figs. 2-35 and 2-36 should be used for calculating $Z^{(0)}$ and $Z^{(1)}$, respectively, for superheated vapors with $0.2 \le P_r \le 10$. $Z^{(0)}$ will approach 1, and $Z^{(1)}$ will approach 0 for $P_r < 0.2$. More accurately, Eq. (2-77) can be used for P_r between 0 and 0.2.

$$Z = 1 + \frac{P_r}{T_r}[(0.1445 + 0.073\omega) - (0.330 - 0.46\omega)T_r^{-1} - (0.1385 + 0.50\omega)T_r^{-2} - (0.0121 + 0.097\omega)T_r^{-3} - 0.0073\omega T_r^{-8}] \quad (2\text{-}77)$$

Extension of the pressure range to $P_r = 14$ is available in the *Technical Data Book*. For saturated vapor densities, the values of $Z^{(0)}$ and $Z^{(1)}$ are tabulated as a

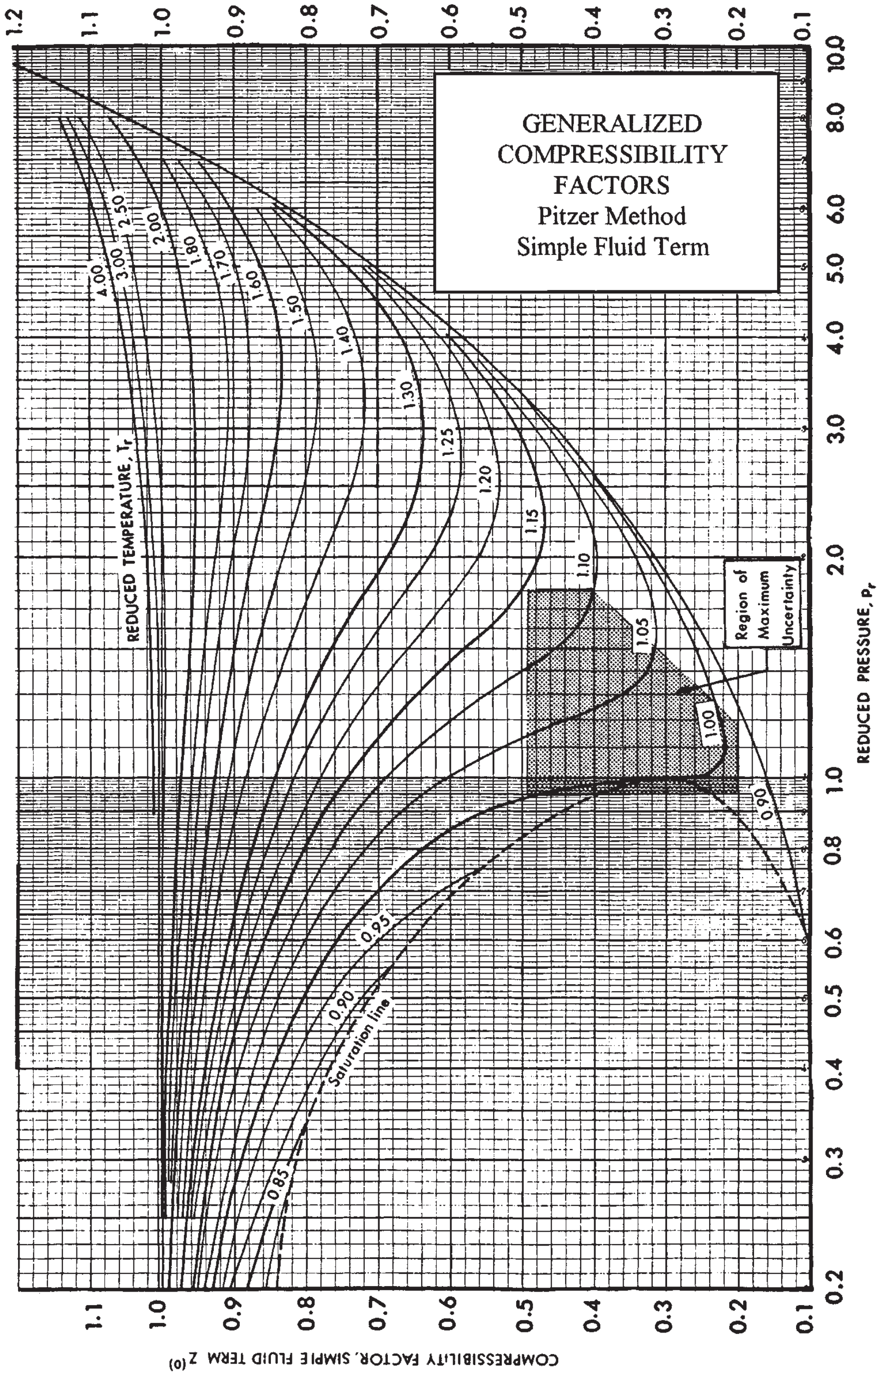

FIG. 2-35 Generalized compressibility factors—Pitzer Method, simple fluid term.

function of reduced pressure in Table 2-395. If the saturation temperature rather than the saturation pressure is known, the vapor pressure of the compound can be determined either from data or the vapor pressure prediction methods discussed earlier.

Example 19 Estimate the molar volume of isobutane at 155°C and 8.6 MPa pressure.

As high pressure, use Eq. (2-75) to calculate Z and then Eq. (2-76) to estimate the molar volume.

The properties of isobutane necessary are $T_c = 135.0°C$, $P_c = 3.647$ MPa, and $\omega = 0.1770$.

$$T_r = \frac{155 + 273.1}{135 + 273.1} = 1.05 \qquad P_r = \frac{8.6}{3.647} = 2.36$$

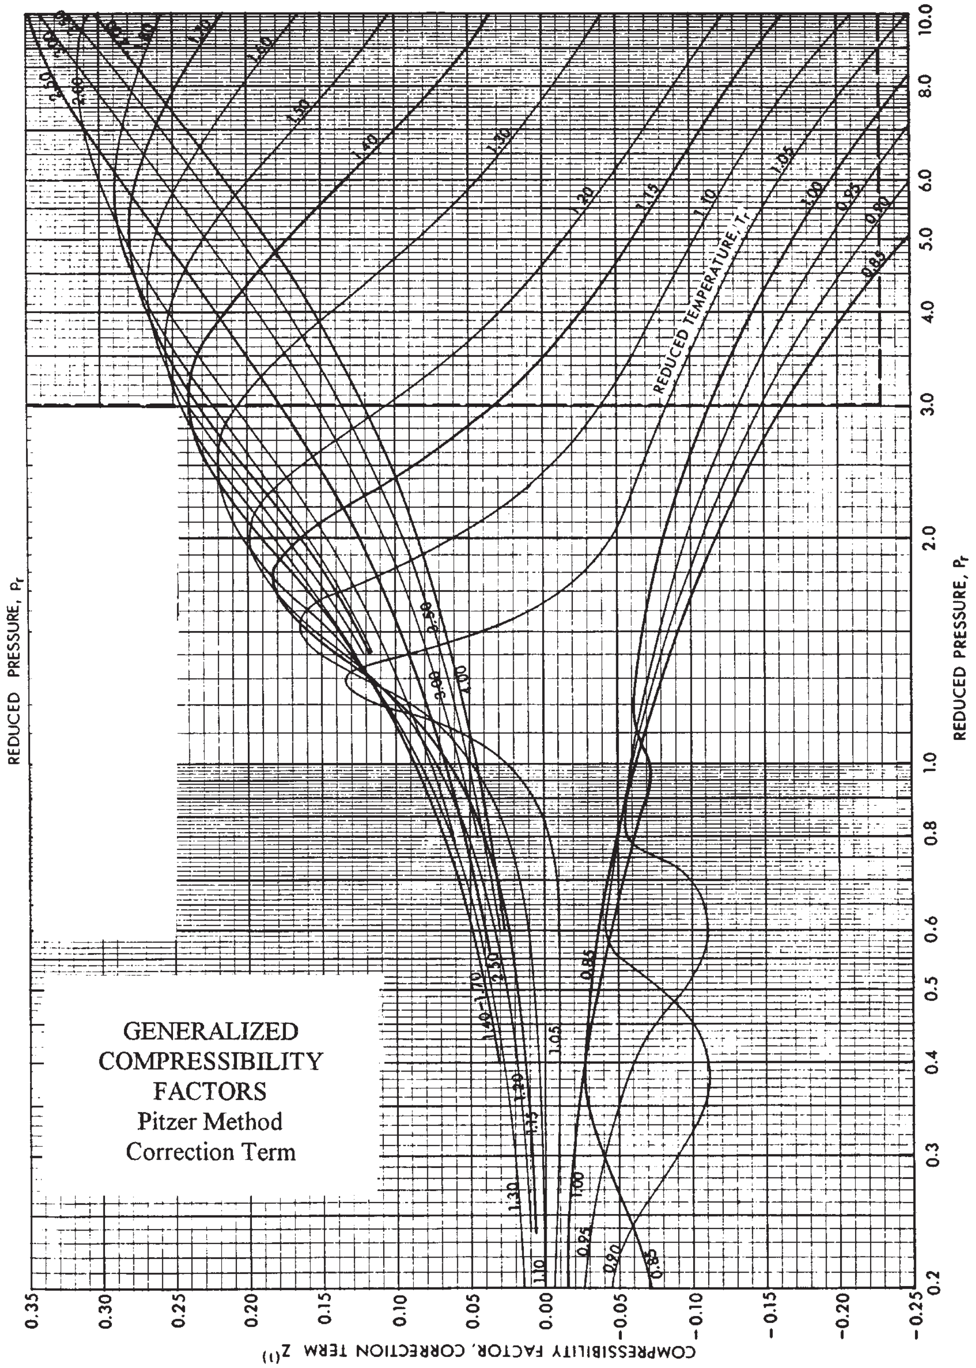

FIG. 2-36 Generalized compressibility factors—Pitzer Method, correction term.

0.70	0.59	−0.075	0.05	0.935	0.000

Using Fig. 2-35, $Z^{(0)} = 0.385$. Using Fig. 2-36, $Z^{(1)} = -0.063$.

$$Z = Z^{(0)} + \omega Z^{(1)}$$

$$Z = 0.385 + 0.1770(-0.063) = 0.374$$

$$V = \frac{ZRT}{P} = \frac{(0.374)(8314)(428.1)}{8.6 \times 10^6}$$

$$V = 0.155 \text{ m}^3\text{/kmol}$$

An experimental value for Z is 0.377.

Note that use of the Lee-Kesler fit [Eq. (2-78)] would give a slightly more accurate answer than the graphical method, and this fit is used for any computer applications.

Lee and Kesler[55] fit the entire Pitzer method to equations, rewriting the basic Eq. (2-75) with respect to a heavy reference fluid (*n*-octane) as shown by Eq. (2-78).

$$Z = Z^{(0)} + \frac{\omega}{\omega^{(h)}}(Z^{(h)} - Z^{(0)}) \qquad (2\text{-}78)$$

where *h* specifies the heavy reference fluid with an acentric factor of 0.3978.

The parameters in the equation are calculated for the simple fluid and the heavy reference fluid with an acentric factor of 0.3978. The parameters in the equation are calculated for the simple fluid and the heavy reference fluid from Eq. (2-79)

$$Z^{(i)} = \frac{P_r V_r}{T_r} = 1 + \frac{B}{V_r} + \frac{C}{V_r^2} + \frac{D}{V_r^5} + \frac{c_4}{T_r^3 V_r^2}\left[\beta + \frac{\gamma}{V_r^2}\right]\exp\left[\frac{-\gamma}{V_r^2}\right] \qquad (2\text{-}79)$$

$$B = b_1 - \left(\frac{b_2}{T_r}\right) - \left(\frac{b_3}{T_r^2}\right) - \left(\frac{b_4}{T_r^3}\right)$$

$$C = c_1 - \left(\frac{c_2}{T_r}\right) - \left(\frac{c_3}{T_r^3}\right)$$

$$D = d_1 + \left(\frac{d_2}{T_r}\right)$$

where $Z^{(i)} = Z^{(0)}$ when the constants in the equation correspond to the simple fluid and $Z^{(h)}$ when the constants in the equation correspond to the heavy reference fluid
P = pressure, kPa
P_c = critical pressure of the compound whose density is sought, kPa
V = molar volume of the simple fluid or the heavy reference fluid, as the case may be, in m³/kmole.
R = gas constant = 8.3140 m³ kPa/k mole K
T_c = critical temperature of the compound whose density is sought, K
T = temperature, K

Constant	Simple fluid	Heavy reference fluid

γ	0.060167	0.03754

For **hydrocarbon and nonpolar gas mixtures,** the Pitzer pure component method can be used to predict vapor density by replacing the true critical properties with pseudocritical properties defined in Eqs. (2-80) and (2-81) by Kay.[47]

$$T_{pc} = \sum_{i=1}^{n} x_i T_{c_i} \qquad (2\text{-}80)$$

$$P_{pc} = \sum_{i=1}^{n} x_i P_{c_i} \qquad (2\text{-}81)$$

The mixture acentric factor, Eq. (2-82), can also be used.

$$\omega = \sum_{i=1}^{n} x_i \omega_i \qquad (2\text{-}82)$$

Errors in compressibility factors tabulated for over 6500 data points rarely exceed 2 percent except in the critical region, where 15 percent errors may be expected and 50 percent errors can occur. For mixtures near the critical point, special techniques are available as discussed in the sixth chapter of the *Technical Data Book*.

For **pure organic vapors,** the Lydersen et al.[63] corresponding states method is the most accurate technique for predicting compressibility factors and, hence, vapor densities. Critical temperature, critical pressure, and critical compressibility factor defined by Eq. (2-21) are used as input parameters. Figure 2-37 is used to predict the compressibility factor at $Z_c = 0.27$, and the result is corrected to the Z_c of the desired fluid using Eq. (2-83).

$$Z = Z_{@ Z_c = 0.27} + D_i(Z_c - 0.27) \qquad (2\text{-}83)$$

D_i is equal to D_a read from Fig. 2-38 if $Z_c > 0.27$; and D_i is equal to D_b read from Fig. 2-39 if $Z_c < 0.27$. At reduced temperatures less than 0.9, D_i can be taken as 0. The density is then calculated from Eq. (2-76). All families of organic compounds except mercaptans and carboxylic acids are predicted within an average deviation of 5 percent.

No specific mixing rules have been tested for predicting compressibility factors for **defined organic mixtures.** However, the Lydersen method using pseudocritical properties as defined in Eqs. (2-80), (2-81), and (2-82) in place of true critical properties will give a reasonable estimate of the compressibility factor and hence the vapor density.

Vapor densities for pure compounds can also be predicted by cubic equations of state. For hydrocarbons, relatively accurate Redlich-Kwong-type equations such as the Soave[98] and Peng-Robinson[81] equations are often used. Both require only T_c, P_c, and ω as inputs. For organic compounds, the Lee-Erbar-Edmister[54] equation (which requires the same input parameters) has been used with errors essentially equivalent to those determined for the Lydersen method. While analytical equations of state are not often used when only densities are required, values from equations of state are used as inputs to equation of state formulations for thermal and equilibrium properties.

Liquid Density Prediction Methods for the prediction of pure saturated hydrocarbons and nonhydrocarbon organics, compressed hydrocarbon liquids, and defined and undefined hydrocarbon mixtures were evaluated. Only the most accurate and convenient methods are included here.

The most convenient method for predicting the saturated liquid density of both **pure hydrocarbons and pure organic liquids** is the method of Rackett[84] as modified by Spencer and Danner.[99] Equation (2-84) is used to calculate the saturated liquid molar density at any temperature using input parameters of T_c, P_c, and Z_{RA}. Z_{RA} is a parameter regressed from experimental data. Values for some common substances are given in Table 2-396. Extensive tabulations are given in the *Technical Data Book*[23] for hydrocarbons and nonhydrocarbons as well as organic and inorganic gases. Additional values are given in the *Data Prediction Manual*[22] for nonhydrocarbons.

$$\frac{1}{\rho_{sat}} = V_{sat} = \left(\frac{RT_c}{P_c}\right) Z_{RA}^n \qquad (2\text{-}84)$$

$$n = 1.0 + (1.0 - T_r)^{2/7}$$

Errors for hydrocarbons between the triple and critical points average about 0.7 percent, with organics averaging about 1.2 percent. The cor-

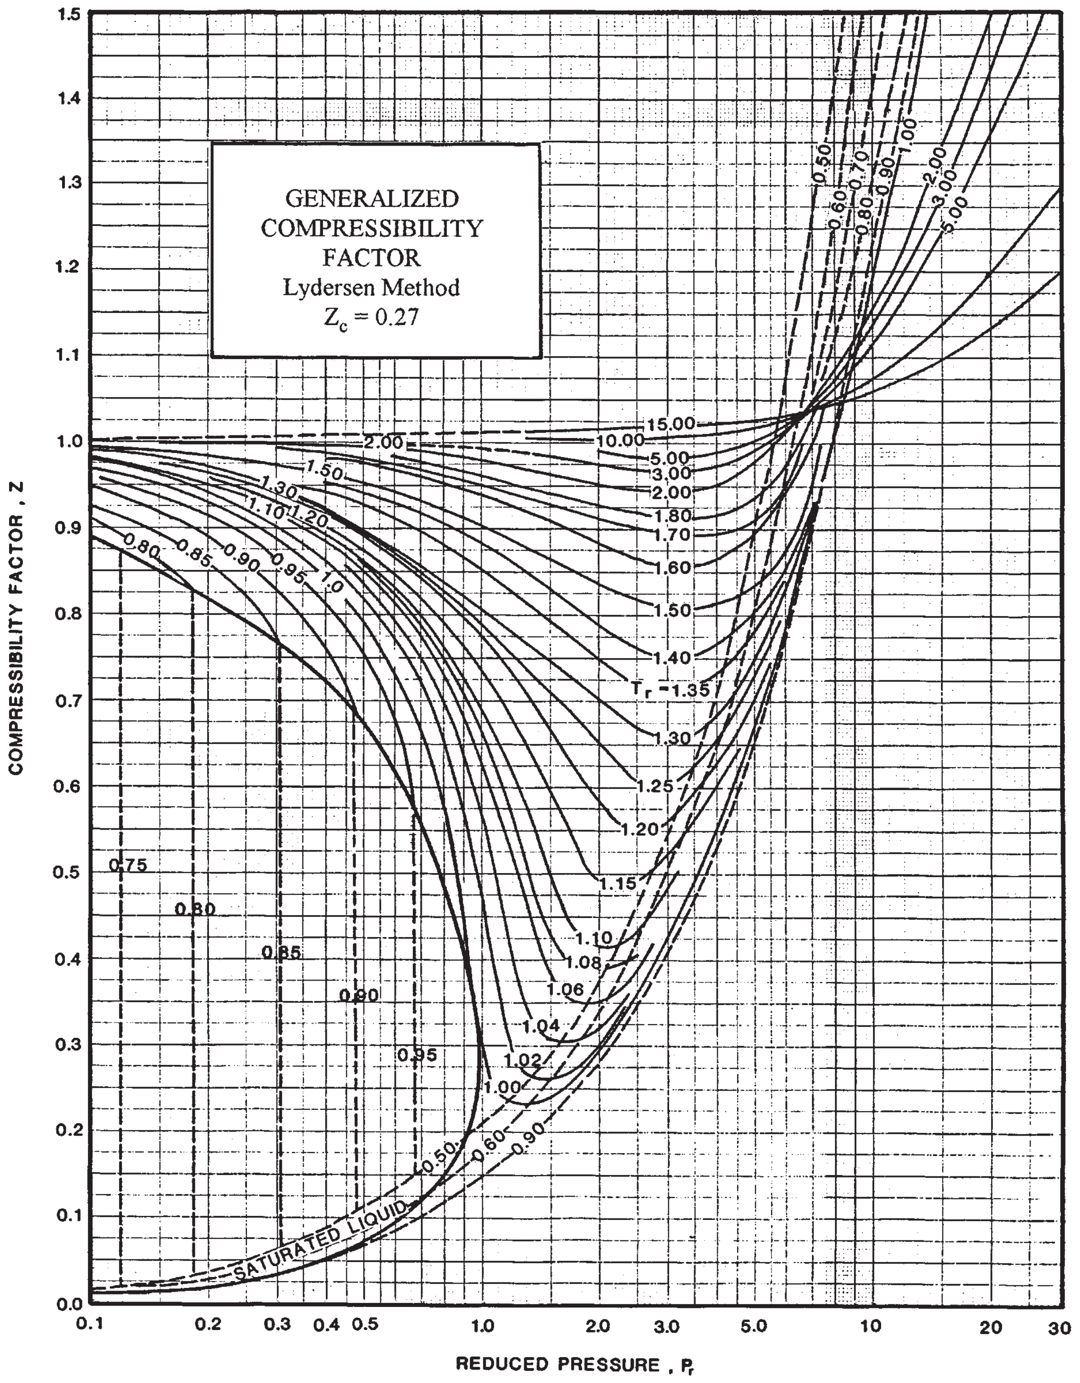

FIG. 2-37 Generalized compressibility factor—Lydersen Method, $Z_c = 0.27$.

relation is especially sensitive to the value of Z_{RA} near the critical point.

If no value of Z_{RA} is available or derivable, the critical compressibility factor can be used in Eq. (2-84) as originally proposed by Rackett. Use of Z_c increases the average error to about 3.0 percent.

Example 20 Estimate the density of saturated liquid propane at 0°C. Use Eq. (2-84).

$$\rho_{sat} = \left(\frac{P_c}{RT_c}\right)\left(\frac{1}{Z_{RA}^n}\right)$$

$$n = 1.0 + (1.0 - T_r)^{2/7}$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

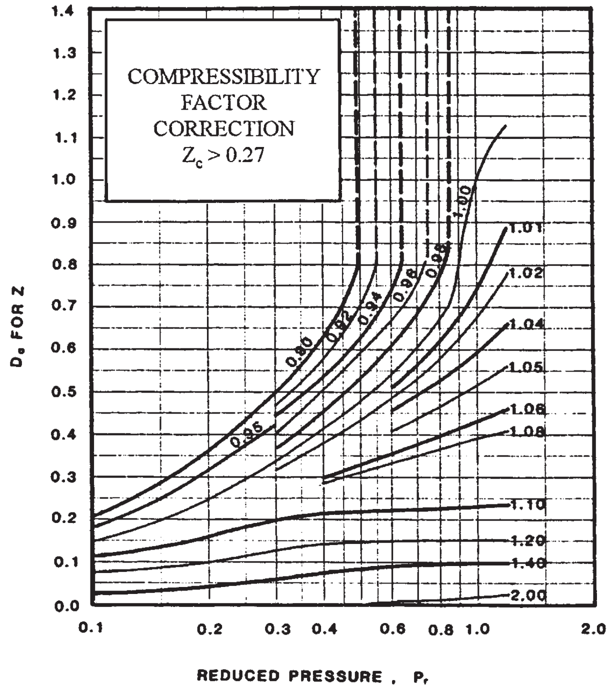

FIG. 2-38 Compressibility factor correction for Lydersen Method, $Z_c > 0.27$.

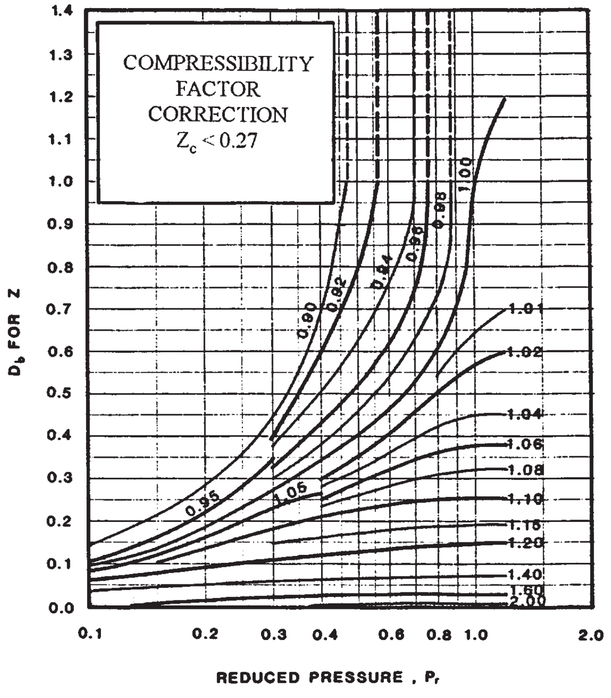

FIG. 2-39 Compressibility factor correction for Lydersen Method, $Z_c < 0.27$.

Pure component properties of propane are $M = 44.1$, $T_c = 96.7°C$, and $P_c = 4.246$ MPa. From Table 2-388, $Z_{RA} = 0.2763$.

$$T_r = \frac{273.1}{369.8} = 0.739, \quad n = 1.0 + (1.0 - 0.739)^{2/7} = 1.6813$$

$$n = 1.6813$$

$$\rho_{sat} = \frac{(4.246 \times 10^6)}{(8314)(369.8)}\left(\frac{1}{0.2763^{1.6813}}\right)$$

$$\rho_{sat} = 1.201 \text{ kmole/m}^3 = 529.6 \text{ kg/m}^3$$

An accepted experimental value is 531 kg/m^3.

An alternate method with approximately the same accuracy as the Rackett method is the COSTALD method of Hankinson and Thomson.[35] The critical temperature, a characteristic volume near the critical volume, and an acentric factor optimized for vapor pressure prediction by the Soave[98] equation of state are required input parameters. The method is detailed in the *Technical Data Book.*[23]

Prediction of the density of **compressed pure liquid hydrocarbons** and their defined mixtures are readily and accurately predicted by the method of Lu.[62] One value of low pressure liquid density and the critical temperature and pressure are required to predict the density at higher pressures from Eq. (2-85).

$$\rho_2 = \left(\frac{C_2}{C_1}\right)\rho_1 \tag{2-85}$$

The constants C_1 and C_2 are both obtained from Fig. 2-40: C_1, usually from the saturated liquid line; and C_2, at the higher pressure. Errors should be less than 1 percent for pure hydrocarbons except at reduced temperatures above 0.95 where errors of up to 10 percent may occur. The method can be used for defined mixtures substituting pseudocritical properties for critical properties. For mixtures, the *Technical Data Book—Petroleum Refining* gives a more complex and accurate mixing rule than merely using the pseudocritical properties. The saturated low pressure value should be obtained from experiment or from prediction procedures discussed in this section for both pure and mixed liquids.

Example 21 Estimate the liquid density of n-nonane at 104.5°C and 6.893 MPa pressure.

A tabulated value of liquid density at 60°F (15.5°C) and 1 atm is 719.8 kg/m^3. Pure component properties are $T_c = 321.5°C$ and $P_c = 2.288$ MPa.

Use Eq. (2-85) to correct a low pressure density.

$$\rho_2 = \left(\frac{C_2}{C_1}\right)\rho_1$$

where ρ_1 is a reference density. C_2 and C_1 are functions of T_r and P_r.

$$T_{r_1} = \frac{288.6}{594.6} = 0.485 \qquad T_{r_2} = \frac{377.6}{594.6} = 0.635$$

$$P_{r_1} = \frac{0.1013}{2.288} = 0.0443 \qquad P_{r_2} = \frac{6.893}{2.288} = 3.013$$

From Fig. 2-40, $C_1 = 1.08$ and $C_2 = 0.998$.

$$\rho_2 = \left(\frac{0.998}{1.08}\right)(719.8) = 665.1 \text{ kg/m}^3$$

An accepted experimental value at this temperature is 658.5 kg/m^3, a 1 percent difference.

An analytical method for the prediction of compressed liquid densities was proposed by Thomson et al.[114] The method requires the saturated liquid density at the temperature of interest, the critical temperature, the critical pressure, an acentric factor (preferably the one optimized for vapor pressure data), and the vapor pressure at the temperature of interest. All properties not known experimentally may be estimated. Errors range from about 1 percent for hydrocarbons to 2 percent for nonhydrocarbons.

For prediction of the densities of a **defined liquid mixture at its bubble point** (ρ_{bp}), the method of Spencer and Danner[100] is the simplest. The density is calculated from Eq. (2-86) using inputs from Eqs. (2-87) and (2-88). For hydrocarbons, T_{mc} is calculated by Eqs. (2-89) through (2-92) if high accuracy is desired or by Eq. (2-93) for a less accurate answer.

$$\frac{1}{\rho_{bp}} = R\left(\sum_{i=1}^{n} x_i \frac{T_{c_i}}{P_{c_i}}\right) Z_{RA_m}^{[1+(1-T_r)^{2/7}]} \tag{2-86}$$

$$Z_{RA_m} = \sum_{i=1}^{n} x_i Z_{RA_i} \tag{2-87}$$

$$T_r = \frac{T}{T_{mc}} \tag{2-88}$$

$$T_{mc} = \sum_{i=1}^{n}\sum_{j=i}^{n} \phi_i \phi_j T_{c_{ij}} \tag{2-89}$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

TABLE 2-396 The Modified Rackett Equation Input Parameters for Calculating Pure Saturated Liquid Densities

Biphenyl	0.2746	Sulfur dioxide	0.2667
Naphthalene	0.2611	Sulfur trioxide	0.2513

$$\phi_i = \frac{x_i V_{c_i}}{\sum_{j=1}^{n} x_j V_{c_j}} \quad (2\text{-}90)$$

$$T_{c_{ij}} = \sqrt{T_{c_i} T_{c_j}}\,(1 - k_{ij}) \quad (2\text{-}91)$$

$$k_{ij} = 1.0 - \left[\frac{\sqrt{V_{c_i}^{1/3} V_{c_j}^{1/3}}}{(V_{c_i}^{1/3} + V_{c_j}^{1/3})/2}\right]^3 \quad (2\text{-}92)$$

$$T_{mc} = \sum_{i=1}^{n} x_i T_{c_i} \quad (2\text{-}93)$$

Errors for binary hydrocarbon systems average about 2.5 percent except near the critical, where errors can approach 20 percent. If inorganic gases are included, errors average 4 percent except at high concentrations of carbon dioxide or hydrogen, where higher errors would be expected. If the simplified method for predicting T_{mc} is used, average errors of 5 to 7 percent should be expected for both binary hydrocarbon and nonhydrocarbon systems. No data are available to test the method for systems with more than two components.

A similarly accurate but slightly more complex method for prediction of densities of defined liquid hydrocarbon mixtures at their bubble points was published by Hankinson and Thomson[35] and was previously cited for prediction of pure liquid hydrocarbons.

For undefined hydrocarbon mixtures, the liquid density may be predicted at any temperature (T) from the mean average boiling point (MeABP) and the specific gravity (sp gr) by Eq. (2-94), adopted from Ritter et al.[92]

$$P = 62.3636\left[(\text{sp gr})^2 - \frac{(1.2655)(\text{sp gr}) - 0.5098 + 8.011 \times 10^{-5}\text{MeABP}(T - 519.67)}{\text{MeABP}}\right]^{1/2} \quad (2\text{-}94)$$

The density is calculated in lb_m/ft^3 if the temperatures are both in °R. Errors average about 0.3 percent at atmospheric pressure. At high pressures, the liquid density of undefined hydrocarbon mixtures can be predicted from the low pressure value by the method of Wright[131] fully outlined in the *Technical Data Book.*[23]

Solid Density Prediction The prediction of solid density is an inexact science and sometimes is taken as the liquid density at the triple point, although the solid density normally is higher than this value with a discontinuity at the triple point. Based on solid density data reviewed for the DIPPR compilation,[24] the solid density at the triple point can be estimated for organic compounds as 1.17 times the liquid density at the triple point. As liquid density at low temperatures varies little with temperature, the density of the liquid at the lowest estimable point above the triple point can be used with little degradation of the result. As solid density only decreases very slightly with increasing temperature and very little data on solid density as a function of temperature exist, no methods have been developed for predicting the solid density vs. temperature.

VISCOSITY

Viscosity is defined as the shear stress per unit area at any point in a confined fluid divided by the velocity gradient in the direction perpendicular to the direction of flow. If this ratio is constant with time at a given temperature and pressure for any species, the fluid is called a Newtonian fluid. This section is limited to Newtonian fluids, which include all gases and most nonpolymeric liquids and their mixtures. Most polymers, pastes, slurries, waxy oils, and some silicate esters are examples of non-Newtonian fluids.

The absolute viscosity (μ) is defined as the sheer stress at a point

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

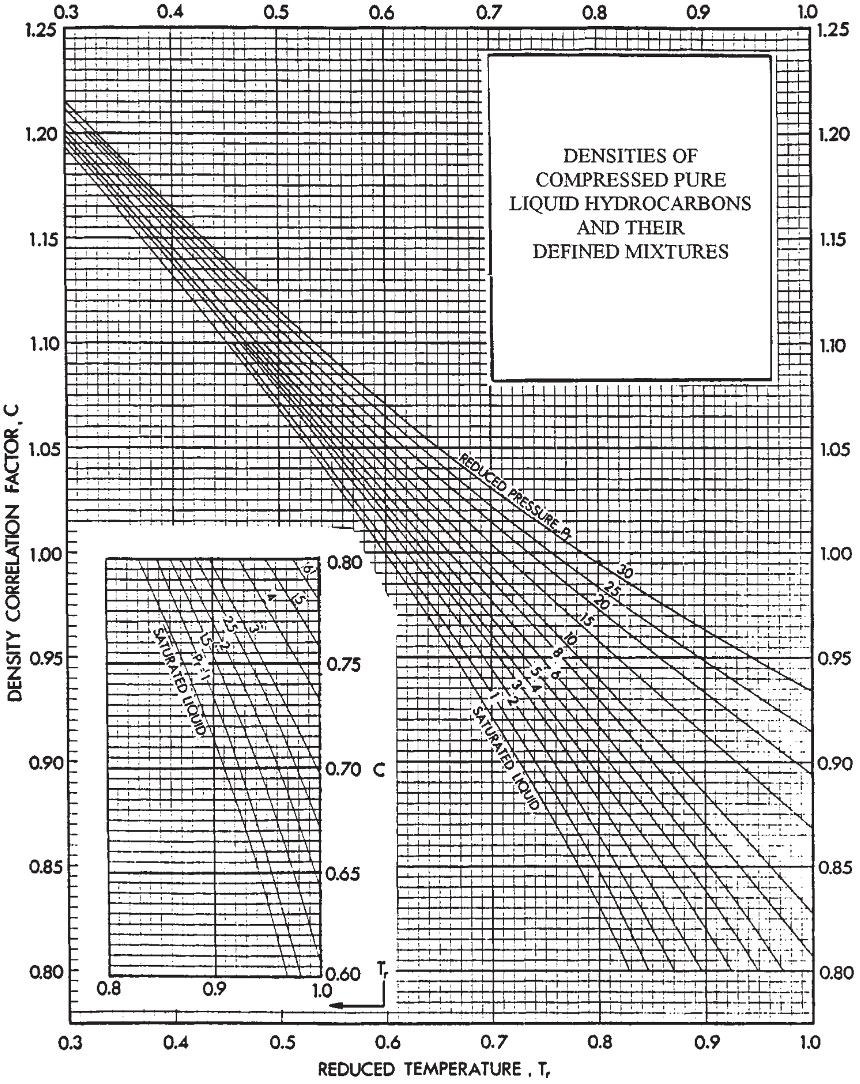

FIG. 2-40 Densities of compressed pure liquid hydrocarbons and their defined mixtures.

divided by the velocity gradient at that point. The most common unit is the poise (1 g/cm sec). The SI unit is the Pa·sec (1 kg/m sec). As many common fluids have viscosities in the hundredths of a poise the centipoise (cp) is often used. One centipoise is then equal to one mPa sec.

The kinematic viscosity (ν) is defined as the ratio of the absolute viscosity to density at the same temperature and pressure. The most common unit corresponding to the poise is the stoke (1 cm^2/sec). The SI unit would be m^2/sec.

Correlation Methods This section briefly discusses methods for correlating viscosities as a function of temperature and presents the most common accurate methods for prediction of vapor and liquid viscosity.

Vapor viscosity is accurately correlated as a function of temperature by Eq. (2-95).

$$\mu_v = \frac{AT^B}{1 + \frac{C}{T} + \frac{D}{T^2}} \tag{2-95}$$

If data are available over a wide range, all four regression constants (*A*, *B*, *C*, and *D*) are usually used. Over narrow temperature ranges, only constants *A* and *B* are necessary.

Liquid viscosity is accurately correlated as a function of temperature by the modified Riedel equation previously discussed for correlation of vapor pressure and shown by Eq. (2-96).

$$\mu_\ell = \exp\left(A + \frac{B}{T} + C \ln (T) + DT^E\right) \tag{2-96}$$

For most systems, only the first three terms are used. Only the first two terms are used for narrow ranges. If data are available in a wide range extending far above the normal boiling point, all four terms are used, with values of *E* varying in integers from −10 to 10 (excluding 0 and −1).

Constants for about 1500 compounds for both viscosities are available in the DIPPR compilation.[24]

Vapor Viscosity Methods for prediction of vapor viscosity abound such that only the most accurate and generally used methods are included.

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

For prediction of the vapor viscosity of **pure hydrocarbons at low pressure** (below T_r of 0.6), the method of Stiel and Thodos[101] is the most accurate. Only the molecular weight, the critical temperature, and the critical pressure are required. Equation (2-97) with values of N from Eqs. (2-98) and (2-99) is used.

$$\mu_v = 4.60 \times 10^{-4} \frac{NM^{1/2}P_c^{2/3}}{T_c^{1/6}} \tag{2-97}$$

$$N = 0.0003400T_r^{0.94} \quad \text{for } T_r \leq 1.5 \tag{2-98}$$

$$N = 0.0001778(4.58T_r - 1.67)^{0.625} \quad \text{for } T_r > 1.5 \tag{2-99}$$

The resultant viscosity is in centipoise (mPa·sec) if T_c and P_c are given in K and Pa, respectively. This method can also be used for light nonhydrocarbon gases except for hydrogen where, special N's are required. For hydrocarbons below ten carbon atoms, average errors of about 3 percent can be expected, with errors increasing to 5–10 percent for heavier hydrocarbons.

Example 22 Estimate the vapor viscosity of propane at 101.3 kPa and 80°C.

Use Eq. (2-97).

$$\mu_v = 4.60 \times 10^{-4} N \frac{M^{1/2}P_c^{2/3}}{T_c^{1/6}}$$

$$T_c = 96.7°\text{C}, \quad P_c = 4.246 \text{ MPa}, \quad \text{and } M = 44.1.$$

To determine whether Eq. (2-98) or (2-99) should be used to calculate N, calculate T_r.

$$T_r = \frac{80 + 273.1}{96.7 + 273.1} = 0.955$$

Use Eq. (2-98): $N = 0.0003400T_r^{0.94}$

Thus, $N = 3.255 \times 10^{-4}$.

$$\mu_v = \frac{(4.60 \times 10^{-4})(3.255 \times 10^{-4})(44.1)^{1/2}(4.246 \times 10^6)^{2/3}}{(369.8)^{1/6}}$$

$$\mu_v = 0.0097 \text{ cp}$$

An experimental value of 0.0095 cp compares favorably.

For prediction of the vapor viscosity of **gaseous mixtures of hydrocarbons and nonhydrocarbon gases at low pressures** below a T_r of 0.6, the method of Bromley and Wilke[13] is recommended.

The mixing rule is given by Eq. (2-100) with the interaction parameter Q for each pair of components defined by Eq. (2-101).

$$\mu_m = \sum_{i=1}^{n} \frac{\mu_i}{1 + \sum_{\substack{j=1 \\ j \neq 1}}^{n} \left(Q_{ij} \frac{x_j}{x_i}\right)} \tag{2-100}$$

$$Q_{ij} = \frac{1 + \left[\left(\frac{\mu_i}{\mu_j}\right)^{1/2}\left(\frac{M_j}{M_i}\right)^{1/4}\right]^2}{\sqrt{8}\left[1 + \frac{M_i}{M_j}\right]^{1/2}} \tag{2-101}$$

Errors, when tested against binary and multicomponent mixtures of both hydrocarbons and nonhydrocarbon gas mixtures, average about 3 percent.

For prediction of the vapor viscosity of **gaseous hydrocarbons and mixtures of hydrocarbons at high pressures** (not applicable to nonhydrocarbon gases) above a T_r of 0.6, low pressure values are calculated from Eq. (2-97) and/or (2-100) and then corrected for pressure by the method of Dean and Stiel[25] given by Eq. (2-102).

$$\mu - \mu_o = 5.0 \times 10^{-8} \frac{M^{1/2}P_c^{2/3}}{T_c^{1/6}} [\exp(1.439\rho_r) - \exp(-1.11\rho_r^{1.858})] \tag{2-102}$$

If critical pressure and critical temperature are given in Pa and K, respectively, viscosities in centipoise result. The variable μ_o is either the low pressure pure component or mixture viscosity according to whether a pure component or mixture is being considered. For mixtures, simple molar average pseudocritical temperature (Kay's rule), pressure, and density, and molar average molecular weight are used. The vapor density can be predicted by the methods previously discussed. Errors of above 5 percent are common for hydrocarbons and their mixtures. Experimental densities will reduce the errors slightly.

Example 23 Estimate the vapor viscosity of a mixture of propane and methane. Assume 60 mole percent methane and 40 mole percent propane at 125°C and 10.34 MPa total pressure. The low pressure viscosity is 0.0123 cp.

Use Eq. (2-102):

$$\mu - \mu_o = 5.0 \times 10^{-8} \frac{M^{1/2}P_c^{2/3}}{T_c^{1/6}} [\exp(1.439\rho_r) - \exp(-1.11\rho_r^{1.858})]$$

Properties of the pure components are:

Methane. $M = 16.04$, $T_c = -110.4°\text{C}$, $P_c = 4.593$ MPa

Propane. $M = 44.10$, $T_c = 96.7°\text{C}$, $P_c = 4.246$ MPa

For the mixture:

$T_{pc} = (0.60)(-110.4 + 273.1) + (0.40)(96.7 + 273.1) = 245.5$ K

$P_{pc} = (0.60)(4.593) + (0.40)(4.246) = 4.454$ MPa

$M_m = (0.60)(16.04) + (0.40)(44.10) = 27.26$

To calculate ρ_r, use Eq. (2-76) to calculate ρ using Pitzer corresponding states first to calculate Z. Then calculate $\rho_r = \rho/\rho_c = \rho V_{pc}$

Additional properties required are:

Methane $\omega = 0.0115$, $V_c = 0.0986$ m³/kmole

Propane $\omega = 0.1523$, $V_c = 0.2002$ m³/kmole

For the mixture:

$\omega_m = (0.60)(0.0115) + (0.40)(0.1523) = 0.0678$

$V_{pc} = (0.60)(0.0986) + (0.40)(0.2002) = 0.1392$ m³/kmole

Using Eq. (2-58): $Z = Z^{(0)} + \omega Z^{(1)}$

$$T_r = \frac{398.1}{245.5} = 1.62 \qquad P_r = \frac{10.34}{4.454} = 2.32$$

From Fig. 2-35: $Z^{(0)} = 0.87$

From Fig. 2-36: $Z^{(0)} \cong 0.20$

$$Z = 0.87 + (0.0678)(.20) = 0.88$$

Hence: $$\rho = \frac{P}{ZRT} = \frac{(10.34)}{(0.88)(8.314 \times 10^{-3})(398.1)}$$

$$\rho = 3.55 \text{ kmole/m}^3$$

$$\rho_r = \rho V_{pc} = (3.55)(.1392) = 0.494$$

$$\mu - \mu_o = \frac{(5.0 \times 10^{-8})(27.26)^{1/2}(4.454 \times 10^6)^{2/3}}{(245.5)^{1/6}} [e^{1.439(.494)} - e^{-1.11(.494)^{1.858}}]$$

$$\mu - \mu_o = \frac{(5.08 \times 10^{-8})(5.22)(27{,}085)}{(2.503)} [2.0358 - 0.7413]$$

$$\mu - \mu_o = 0.0037$$

$$\mu = 0.0037 + 0.0123 = 0.0160 \text{ cp}$$

An experimental value of 0.0167 cp compares favorably.

For **pure nonhydrocarbon polar gases at low pressures,** the viscosity can be estimated by the method of Reichenberg[85] given by Eq. (2-103).

$$\mu = \frac{AT_r}{[1 + 0.36T_r(T_r - 1)]^{1/6}} \tag{2-103}$$

For organic compounds:

$$A = \frac{M^{1/2}T_c}{\sum n_i C_i} \tag{2-104}$$

For inorganic gases:

$$A = 1.6104 \times 10^{-10} \left[\frac{M^{1/2}P_c^{2/3}}{T_c^{1/6}}\right] \tag{2-105}$$

Viscosities are calculated in Pa sec (10^3 cp = 1 Pa sec) with T_c in K and P_c in Pa. Group contributions based on atomic structure for organic compounds necessary for Eq. (2-104) are tabulated in Table 2-397. Errors average about 5 percent for most organics, with slightly higher errors for inorganic gases. For pure nonhydrocarbon nonpolar gases, an alternate method is the method of Yoon and Thodos,[132] which requires the same input parameters as the Reichenberg method. The method, when evaluated for the *Technical Data Manual,* showed errors of about 3 percent for compounds with low dipole moments and requires special correlations for hydrogen and helium.

Example 24 Estimate the vapor viscosity of isopropyl alcohol at 251°C and atmospheric pressure.

Use Eq. (2-103) with A determined from Eq. (2-104).

$$\mu = \frac{AT_r}{[1 + 0.36T_r(T_r - 1)]^{1/6}}$$

$$A = \frac{M^{1/2}T_c}{\sum n_i C_i}$$

TABLE 2-397 Group Contribution Values for Eq. (2-104)

Group	Contribution $C_i \times 10^{-8}$ m·s·K/kg
$-CH_3$	0.904
$>CH_2$ (nonring)	0.647
$>CH-$ (nonring)	0.267
$>C<$ (nonring)	−0.153
$=CH_2$	0.768
$=CH-$ (nonring)	0.553
$>C=$ (nonring)	0.178
$\equiv CH$	0.741
$\equiv C-$ (nonring)	0.524
$>CH_2$ (ring)	0.691
$>CH-$ (ring)	0.116
$>C<$ (ring)	0.023
$=CH-$ (ring)	0.590
$>C=$ (ring)	0.359
$-F$	0.446
$-Cl$	1.006
$-Br$	1.283
$-OH$ (alcohols)	0.796
$>O$ (nonring)	0.359
$>C=O$ (nonring)	1.202
$-CHO$ (aldehydes)	1.402
$-COOH$ (acids)	1.865
$-COO-$ (esters) or $HCOO-$ (formates)	1.341
$-NH_2$	0.971
$>NH$ (nonring)	0.368
$=N-$ (ring)	0.497
$-CN$	1.813
$>S$ (ring)	0.886

Pure component properties are $T_c = 508.3$ K and $M = 60.1$.
Isopropyl alcohol group contributions for $\sum n_i C_i$ are calculated using Table 2-397.

$$2\ -CH_3 \text{ groups} = (2)(.904 \times 10^8) +$$

$$1\ >CH- \text{ group} = (1)(.267 \times 10^8) +$$

$$1\ -OH \text{ group} = (1)(.796 \times 10^8) = 2.871 \times 10^8$$

$$T_r = \frac{524.1}{508.3} = 1.031$$

$$A = \frac{60.1^{1/2}(508.3)}{2.871} \times 10^8 = 1.373 \times 10^{-5} \text{ Pa sec}$$

$$\mu = \frac{(1.373 \times 10^{-5})(1.031)}{[1 + 0.36(1.031)(.031)]^{1/6}} = 1.413 \times 10^{-5} \text{ Pa sec}$$

(An experimental value of 1.380×10^{-5} Pa sec compares favorably.)

For **pure nonhydrocarbon polar and nonpolar gases at high pressure,** a method of prediction attributed to Stiel and Thodos[102] depending on the reduced density as a corrector to the low pressure gas viscosity (μ^o) takes various forms for polar gases according to the reduced density (ρ_r) as shown in Eqs. (2-106) through (2-109).

$$\rho_r \le 0.1 \qquad (\mu - \mu^o)B = 1.656 \times 10^{-7}\rho_r^{1.111} \qquad (2\text{-}106)$$

$$0.1 \le \rho_r \le 0.9 \qquad (\mu - \mu^o)B = 6.07 \times 10^{-9}(9.045\rho_r + 0.63)^{1.739} \qquad (2\text{-}107)$$

$$0.9 \le \rho_r < 2.2 \qquad \log\{4 - \log_{10}[(\mu - \mu^o)10^7 B]\} = 0.6439 - 0.1005\rho_r \qquad (2\text{-}108)$$

$$2.2 \le \rho_r < 2.6 \qquad \log\{4 - \log_{10}[(\mu - \mu^o)10^7 B]\} = 0.6439 - 0.1005\rho_r - 4.75 \times 10^{-4}(\rho_r^3 - 10.65)^2 \qquad (2\text{-}109)$$

$$B = 2173.424\, T_c^{1/6} M^{-1/2} P_c^{-2/3} \qquad (2\text{-}110)$$

For nonpolar gases, Jossi et al.[45] extended the method as shown in Eq. (2-111) for $0.1 < \rho_r < 3.0$.

$$[(\mu - \mu^o)B10^7 + 1]^{1/4} = 1.0230 + 0.23364\rho_r + 0.58533\rho_r^2 - 0.40758\rho_r^3 + 0.093324\rho_r^4 \qquad (2\text{-}111)$$

In all cases viscosities are in Pa sec with T_c in K and P_c in Pa. For nonpolars, errors are very small; while for polars, average errors reach 11 percent.

Example 25 Estimate the vapor viscosity of carbon dioxide at 350 K and a total pressure of 20 MPa. An experimental low pressure viscosity at 350 K is 1.7386×10^{-5} Pa sec.

Use Eq. (2-111) with B calculated by Eq. (2-110).

The pure component properties necessary are $T_c = 304.19$ K, $P_c = 7.3815$ MPa, $V_c = 0.094$ m³/kmole, and $M = 44.01$.

Using the Lee-Kesler form of the Pitzer method [Eq. (2-78)], $Z = 0.4983$.

$$\rho_r = \frac{V_c}{V} = \frac{V_c P}{ZRT} = \frac{(0.094)(2 \times 10^7)}{(0.4983)(8314)(350)} = 1.2965$$

$$B = \frac{2173.424 T_c^{1/6}}{M^{1/2} P_c^{2/3}} = \frac{(2173.424)(304.19)^{1/6}}{(44.01)^{1/2}(7.3815 \times 10^6)^{2/3}}$$

$$B = 2.2411 \times 10^{-2}$$

$$[(\mu - \mu^o)B10^7 + 1]^{1/4} = 1.0230 + 0.23364(1.2965) + 0.58533(1.2965)^2 - 0.40758(1.2965)^3 + 0.093324(1.2965)^4 = 1.6852$$

$$(\mu - 1.7386 \times 10^{-5})(2.2411 \times 10^{-2})(10^7) + 1 = 8.0659$$

$$\mu - 1.7386 \times 10^{-5} = 3.1529 \times 10^{-5}$$

$$\mu = 4.89 \times 10^{-5} \text{ Pa sec}$$

An experimental value of 4.73×10^{-5} Pa sec compares favorably.

For both polar and nonpolar **nonhydrocarbon gaseous mixtures at low pressures,** the most accurate viscosity prediction method is the method of Brokaw.[10,11] The method is quite accurate but requires the dipole moment and the Stockmayer energy parameter (ε/k) for polar components as well as pure component viscosities, molecular weights, the normal boiling point, and the liquid molar volume at the normal boiling point. The *Technical Data Manual* should be consulted for the full method.

For nonpolar, nonhydrocarbon vapor mixtures at high pressures, the method of Dean and Stiel[25] [Eq. (2-102)] discussed earlier can be used. The accuracy of the method is excellent and dependent on the pure component viscosity values used as input parameters.

Liquid Viscosity The viscosity of both **pure hydrocarbon and pure nonhydrocarbon liquids** are most accurately predicted by the method of van Velzen et al.[122] The basic equation (2-112) depends on group contributions which are dependent on structure for the calculation of compound-specific constants B and T_o.

$$\log \mu = B\left(\frac{1}{T} - \frac{1}{T_o}\right) - 3.0 \qquad (2\text{-}112)$$

Resultant viscosities are in Pa sec. If the −3.0 on the right is deleted, answers are in cp. T_o is calculated by Eq. (2-114) or (2-115) according to the value of an adjusted carbon number N^* calculated by Eq. (2-113) using the actual carbon number N and group contributions from Table 2-398.

$$N^* = N + \sum_i \Delta N_i \qquad (2\text{-}113)$$

$$N^* \le 20 \quad T_o = 28.86 + 37.439N^* - 1.3547N^{*2} + 0.02076N^{*3} \qquad (2\text{-}114)$$

$$N^* > 20 \quad T_o = 8.164N^* + 238.59 \qquad (2\text{-}115)$$

TABLE 2-398 Group Contribution Values for Liquid Viscosity Prediction

Structures or functional group	ΔN_i	ΔB_i	Remarks
n-Alkanes	0	0	
Isoalkanes	$1.389 - 0.238N$	15.51	
Saturated hydrocarbons with two methyl groups in isoposition	$2.319 - 0.238N$	15.51	
n-Alkanes	$-0.152 - 0.042N$	$-44.94 + 5.410N^*$	
n-Alkadienes	$-0.304 - 0.084N$	$-44.94 + 5.410N^*$	
Isoalkanes	$1.237 - 0.280N$	$-36.01 + 5.410N^*$	
Isoalkadienes	$1.085 - 0.322N$	$-36.01 + 5.410N^*$	
Hydrocarbon with one double bond and two methyl groups in isoposition	$2.626 - 0.518N$	$-36.01 + 5.410N^*$	For any additional CH_3 groups in isoposition, increase ΔN by $1.389 - 0.238N$
Hydrocarbon with two double bonds and two methyl groups in isoposition	$2.474 - 0.560N$	$-36.01 + 5.410N^*$	For any additional CH_3 groups in isoposition, increase ΔN by $1.389 - 0.238N$
Cyclopentanes	$0.205 + 0.069N$	$-45.96 + 2.224N^*$	$N \le 16$; not recommended for $N = 5,6$
	$3.971 - 0.172N$	$-339.67 + 23.135N^*$	$N \ge 16$
Cyclohexanes	1.48	$-272.85 + 25.041N^*$	$N < 17$; not recommended for $N = 6,7$
	$6.517 - 0.311N$	$-272.85 + 25.041N^*$	$N \ge 17$
Alkyl benzenes	0.60	$-140.04 + 13.869N^*$	$N < 16$; not recommended for $N = 6,7$[a,e,f]
	$3.055 - 0.161N$	$-140.04 + 13.869N^*$	$N \ge 16$[a,e,f]
Polyphenols	$-5.340 + 0.815N$	$-188.40 + 9.558N^*$	[a]
Alcohols			
Primary	$10.606 - 0.276N$	$-589.44 + 70.519N^*$	[b]
Secondary	$11.200 - 0.605N$	497.58	[b]
Tertiary	$11.200 - 0.605N$	928.83	[b]
Diols (correction)	See remarks	557.77	For ΔN, use alcohol contributions and add $N - 2.50$
Phenols (correction)	$16.17 - N$	213.68	[a,c,d]
—OH on side chain to aromatic ring (correction)	−0.16	213.68	
Acids	$6.795 + 0.365N$	$-249.12 + 22.449N^*$	$N < 11$, not recommended for $N = 1,2$
	10.71	$-249.12 + 22.449N^*$	$N \ge 11$
Isoacids	See remarks	$-249.12 + 22.449N^*$	Calculate ΔB as for straight-chain acid; calculate ΔN for straight-chain acid but reduce ΔN by 0.24 for each methyl group in isoposition
Acids with aromatic nucleus in structure (correction)	4.81	$-188.40 + 9.558N^*$	
Esters	$4.337 - 0.230N$	$-149.13 + 18.695N^*$	If hydrocarbon groups have isoconfiguration, see [e]
Esters with aromatic nucleus in structure (correction)	$-1.174 + 0.376N$	$-140.04 + 13.869N^*$	Add to values of ΔN, ΔB calculated for ester
Ketones	$3.265 - 0.122N$	$-117.21 + 15.781N^*$	If hydrocarbon groups have isoconfiguration, see [e]
Ketones with aromatic nucleus in structure (correction)	2.70	$-760.65 + 50.478N^*$	Add to values of ΔN, ΔB calculated for ketone
Ethers	$0.298 + 0.209N$	$-9.39 + 2.848N^*$	If hydrocarbon groups have isoconfiguration, see [e]
Aromatic ethers	$11.5 - N$	$-140.04 + 13.869N^*$	The ΔN value is not a correction to regular ether value, but the ΔB value is a correction to regular ether[c]
Amines			
Primary	$3.581 + 0.325N$	$25.39 + 8.744N^*$	If hydrocarbon groups have isoconfiguration, see [e]
Primary amine in side chain of aromatic compound (correction)	−0.16	0	Corrections to be added to amine calculation[e]
Secondary	$1.390 - 0.461N$	$25.39 + 8.744N^*$	If hydrocarbon groups have isoconfiguration, see [e]
Tertiary	3.27	$25.39 + 8.744N^*$	If hydrocarbon groups have isoconfiguration, see [e]
Primary amines with NH_2 group on aromatic nucleus	$15.04 - N$	0	The ΔN value is not a correction to regular amine value; to find ΔB, use primary amine value[a,c]
Secondary or tertiary amine with at least one aromatic group attached to amino nitrogen	[f]	[f]	
Nitro compounds			
1-Nitro	$7.812 - 0.236N$	$-213.14 + 18.330N^*$	
2-Nitro	5.84	$-213.4 + 18.330N^*$	Note alkene contribution is necessary
3-Nitro	5.56	$-338.01 + 25.086N^*$	
4-Nitro; 5-Nitro	5.36	$-338.01 + 25.086N^*$	
Aromatic nitrocompounds	$7.182 - 0.236N$	$-213.14 + 18.330N^*$	For aromatic correction, see [f]
Nitrile	$4.039 - 0.0103N$	$-241.66 + 27.937N^*$

TABLE 2-398 Group Contribution Values for Liquid Viscosity Prediction (*Concluded*)

Structures or functional group	ΔN_i	ΔB_i	Remarks
Amines (*Cont.*)			
Isomethyl on nitrile	$-0.7228 + 0.1755N$	$286.26 - 31.009N^*$	
Aromatic nitrile	$2.321 - 0.2357N$	$-26.063 - 11.516N^*$	
Dinitrile	$10.452 - 1.1276N$	$3599.9 - 199.96N^*$	
Halogenated compounds			
Fluoride	1.43	5.75	
Chloride	3.21	−17.03	[e,f]
Bromide	4.39	$-101.97 + 5.954N^*$	[e,f]
Iodide	5.76	−85.32	[e,f]
Special configurations (corrections)			
$C(Cl)_x$	$1.91 - 1.459x$	−26.38	
—CCl—CCl—	0.96	0	
$—C(Br)_x—$	0.50	$81.34 - 86.850x$	
—CBr—CBr—	1.60	−57.73	
CF_3			
In alcohols	−3.93	341.68	
In other compounds	−3.93	25.55	
Aldehydes	3.38	$146.45 - 25.11N^*$	
Aldehydes with an aromatic nucleus in structure (correction)	2.70	$-760.65 + 50.478N^*$	
Anhydrides	$7.97 - 0.50N$	−33.50	
Anhydrides with an aromatic nucleus in structure (correction)	2.70	$-760.65 + 50.478N^*$	
Amides	$13.12 + 1.49N$	$524.63 - 20.72N^*$	
Amides with an aromatic nucleus in structure (correction)	2.70	$-760.65 + 50.478N^*$	
Sulfide	$3.9965 - 0.1861N$	$-76.676 + 8.1403N^*$	
Isomethyl on sulfide	0.1601	−25.026	

[a] For substitutions on an aromatic nucleus in more than one position, additional corrections are required:

Ortho	$\Delta N = 0.51$	$\Delta B = \begin{cases} -571.94 \text{ (with —OH)} \\ 54.84 \text{ (without —OH)} \end{cases}$
Meta	$\Delta N = 0.11$	$\Delta B = 27.25$
Para	$\Delta N = -0.04$	$\Delta B = 17.57$

[b] For alcohols, if there is a methyl group in the isoposition, increase ΔN by 0.24 and ΔB by 94.23.

[c] If the compound has an aromatic —OH or $—NH_2$, or if there is an aromatic ether, use ΔN contribution in table but neglect other substituents on the ring such as halogen, CH_3, NO_2, and the like. For the calculation of ΔB, however, such substituents must be taken into account.

[d] For aromatic alcohols and compounds with an —OH on a side chain, the alcohol contribution (primary, etc.) must be included. For example, *o*-chlorophenol:

$\Delta B = \Delta B$ (primary alcohol) + ΔB (chlorine) + ΔB (phenol) + ΔB (ortho correction—see footnote *a*)

With $N^* = 16.17$ (see footnote *c*):

$\Delta B = (-589.44 + 70.519 \times 16.17) + (-17.03) + (213.68) + (-571.94) = 175.56$

$B_a = 745.94 \quad B = B_a + \Delta B = 921.50$

2-Phenylethanol:

$N = 8$; $\Delta N = \Delta N$ (primary alcohol) + ΔN (correction) = $[10.606 - (0.276)(8)] + (-0.16) = 8.24$

$N^* = N + \Delta N = 8 + 8.24 = 16.24$

$\Delta B = \Delta B$ (primary alcohol) + ΔB (correction) = $[-589.44 + (70.519)(16.24)] + 213.68 = 769.47$

$B_a = 747.43 \quad B = B_a + \Delta B = 1516.9$

[e] For esters, alkylbenzenes, halogenated hydrocarbons, and ketones: If the hydrocarbon chain has a methyl group in an isoposition, decrease ΔN by 0.24 and increase ΔB by 8.93 for each such grouping. For ethers and amines, decrease ΔN by 0.50 and increase ΔB by 8.93 for each isogroup.

[f] For alkylbenzenes, nitrobenzenes, halogenated benzenes and for secondary or tertiary amines where at least one aromatic group is connected to an amino nitrogen, add the following corrections for each aromatic nucleus. If $N < 16$, increase ΔN by 0.60; if $N \geq 16$, increase ΔN by $3.055 - 0.161N$ for each aromatic group. For any N, increase ΔB by $(-140.04 + 13.869N^*)$.

From van Velzen et al. (122).

B is calculated by Eq. (2-116) using values of B_a calculated from Eq. (2-117) or (2-118) according to the value of N^* and group contributions from Table 2-398.

$$B = B_a + \sum_i \Delta B_i \tag{2-116}$$

$$N^* \leq 20 \quad B_a = 24.79 + 66.885N^* - 1.3173N^{*2} - 0.00377N^{*3} \tag{2-117}$$

$$N^* > 20 \quad B_a = 530.59 + 13.740N^* \tag{2-118}$$

The method should not be used for the first member of a homologous series or for temperatures much above the normal boiling point ($T_r \approx 0.75$). Errors for both hydrocarbons and nonhydrocarbons average 15 percent for a wide variety of compounds. Higher errors are noted for amines, diols, ethers, and fluorides. Table 2-398 gives ΔN and ΔB contributions for most common groups. Space prohibits examples for each type of compound or inclusion of specialized cases that are more fully discussed in the *Technical Data Manual.*

Example 26 Estimate the liquid viscosity of *cis*-1,4-dimethylcyclohexane at 0°C.

Use Eq. (2-112) with N^* calculated from Eq. (2-113) and B calculated from Eq. (2-116).

Determine group contributions from Table 2-398.

		ΔN_i	ΔB_i
Cyclohexanes	(1)	1.48	$-272.85 + 25.041\,N^*$
n-Alkanes	(2)	0	0

$$N^* = N + \sum_i n_i \Delta N_i$$

$$N^* = 8 + (1)(1.48) + (2)(0) = 9.48$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Use Eq. (2-114) to calculate T_o:

$$T_o = 28.86 + 37.439(9.48) - 1.3547(9.48)^2 + (.02076)(9.48)^3$$

$$T_o = 279.72$$

$$B = B_a + \sum_i n_i \Delta B_i$$

Use Eq. (2-117) to calculate B_a:

$$B_a = 24.79 + 66.885(9.48) - 1.3173(9.48)^2 - 0.00377(9.48)^3$$

$$B_a = 537.26$$

$$B = 537.26 + (1)[-272.85 + 25.041\ (9.48)]$$

$$B = 501.80$$

$$\log \mu = B\left(\frac{1}{T} - \frac{1}{T_o}\right) - 3.0$$

$$\log \mu = 501.80\left(\frac{1}{273.15} - \frac{1}{279.72}\right) - 3.0$$

$$\log \mu = -2.9569$$

$$\mu = 0.001104 \text{ Pa sec} = 1.104 \text{ cp}$$

An experimental value at 0°C is 1.224 cp.

A mixing rule developed by Kendall and Monroe[48] is useful for determining the **liquid viscosity of defined hydrocarbon mixtures.** Equation (2-119) depends only on the pure component viscosities at the given temperature and pressure and the mixture composition.

$$\mu_m = \left(\sum_{i=1}^{n} x_i \mu_i^{1/3}\right)^3 \qquad (2\text{-}119)$$

For mixtures of the same chemical family, errors average less than 3 percent, while errors overall average 5–6 percent, with errors of mixed families averaging from 10–15 percent.

For estimating the liquid viscosity of **defined nonhydrocarbon mixtures,** a mixing rule shown by Eq. (2-120) was recommended by the *Technical Data Manual.*

$$\ln \mu_m = \sum_i x_i \ln \mu_i \qquad (2\text{-}120)$$

Errors average near 15 percent.

For interpolating viscosities of hydrocarbon mixtures within a limited range knowing viscosities at two temperatures, ASTM Procedure D341-89, including both charts and equations, is recommended. Several recommended methods for predicting the viscosity of undefined hydrocarbon mixtures, such as petroleum fractions and coal liquids, are presented and evaluated in the *Technical Data Book—Petroleum Refining.* In addition, several methods for determining the liquid viscosity of blends of hydrocarbon mixtures and a method for liquid viscosity of pure hydrocarbons blended with undefined mixtures are given.

The most accurate method for predicting the liquid viscosity of **hydrocarbons containing fewer than 20 carbon atoms at high pressure** is a corresponding states method developed by Graboski and included in the *Technical Data Book—Petroleum Refining.* Critical temperature, critical pressure, the acentric factor, and knowing or being able to calculate at least one viscosity at a reference temperature and pressure are required. Errors average about 5 percent. For high molecular weight hydrocarbons at high pressure, low pressure viscosities can be converted instead of using the method of Kouzel,[51] which requires a low pressure liquid viscosity as input. Compounds of more than 20 carbon atoms and their mixtures are treated in this way.

For predicting the **liquid viscosity of pure hydrocarbon mixtures at high temperatures,** the method of Letsou and Stiel[58] is available. Error analyses with only a small amount of data shows errors averaging 34 percent in the reduced temperature range of 0.76 to 0.98. Equation (2-121) defines the method with inputs of Eqs. (2-122) and (2-123).

$$\mu\left(2173.424\,\frac{T_c^{1/6}}{M^{1/2}P_c^{2/3}}\right) = \mu^{(0)} + \omega\mu^{(1)} \qquad (2\text{-}121)$$

$$\mu^{(0)} = 1.5174 \times 10^{-5} - 2.135 \times 10^{-5} T_r + 7.5 \times 10^{-6} T_r^2 \qquad (2\text{-}122)$$

$$\mu^{(1)} = 4.2552 \times 10^{-5} - 7.674 \times 10^{-5} T_r + 3.4 \times 10^{-5} T_r^2 \qquad (2\text{-}123)$$

Results are in Pa sec with inputs of T_c in K and P_c in Pa.

VAPOR AND LIQUID THERMAL CONDUCTIVITY

Thermal conductivity describes the ease with which conductive heat can flow through a vapor, liquid, or solid layer of a substance. It is defined as the proportionality constant in Fourier's law of heat conduction in units of energy · length/time · area · temperature; e.g., W/m K.

Gases For **pure component, low pressure** (<350 kPa) **hydrocarbon** gases, Misic and Thodos[70,71] recommend the following equations. For **methane** and **cyclic compounds** below reduced temperatures of 1.0:

$$k_G = 4.45 \times 10^{-7}\, T_r \frac{C_p}{\lambda} \qquad (2\text{-}124)$$

For these hydrocarbons above reduced temperatures of 1.0 and for other hydrocarbons at any temperature:

$$k_G = 10^{-7}\,(14.52\,T_r - 5.14)^{2/3}\left(\frac{C_p}{\lambda}\right) \qquad (2\text{-}125)$$

In these equations,

$$\lambda = T_c^{1/6} M^{1/2} \left(\frac{101.325}{P_c}\right)^{2/3} \qquad (2\text{-}126)$$

where k_G = vapor thermal conductivity, W/m K
T_r = reduced temperature, T/T_c
T = temperature, K
T_c = critical temperature, K
C_p = heat capacity at constant pressure, J/kmol K
M = molecular weight
P_c = critical pressure, kPa

C_p may be assumed to be the ideal gas heat capacity, C_p^o. Average errors can be expected to be less than 5 percent.

Example 27 Estimate thermal conductivity for *n*-hexane. For *n*-hexane at 373.15 K and low pressure, the required properties from Daubert et al.[24] are: T_c = 507.6 K, M = 86.18, P_c = 3025.0 kPa, and $C_p^o = 1.721 \times 10^5$. T_r = 373.15/507.6 = 0.7351. Using Eq. (2-126):

$$\lambda = (507.6)^{1/6}\,(86.18)^{1/2}\left(\frac{101.325}{3025.0}\right)^{2/3}$$

$$\lambda = 2.724$$

Substituting into Eq. (2-125):

$$k_G = 10^{-7}\,[(14.52)(0.7351) - 5.14]^{2/3}\left(\frac{1.721 \times 10^5}{2.724}\right)$$

$$k_G = 0.01977 \text{ W/m K}$$

The reported value is 0.02025 W/m K.[24]

For **pure nonhydrocarbon** gases at low pressures (up through 1 atm), the following equations may be used at temperature T (K):

Monatomic gases[12]: $$k_G = 2.5\,\frac{\eta_G C_v}{M} \qquad (2\text{-}127)$$

Linear molecules[12]: $$k_G = \frac{\eta_G}{M}\left(1.30\,C_v + 14644.0 - \frac{2928.8}{T_r}\right) \qquad (2\text{-}128)$$

Nonlinear molecules[102]: $$k_G = \frac{\eta_G}{M}\,(1.15\,C_v + 16903.36) \qquad (2\text{-}129)$$

where k_G = vapor thermal conductivity, W/m K
η_G = vapor viscosity, Pa·s
C_v = heat capacity at constant volume, J/kmol K
M = molecular weight
T_r = reduced temperature, T/T_c
T_c = critical temperature, K

C_v may be calculated as $C_p^o - R$, where C_p^o is the ideal gas heat capacity in J/kmol K and R is the gas constant, 8314 J/kmol K. Average errors are in the 8–10 percent range but may be higher for polar compounds. This method should not be used for molecules that associate; e.g., organic acids.

Example 28 Estimate thermal conductivity of carbon dioxide at 370 K and low pressure. For carbon dioxide (a linear molecule) at 370.0 K and low pressure, the required properties from Daubert et al.[24] are: T_c = 304.2 K, $\eta_G = 1.828 \times 10^{-5}$ Pa·s, M = 44.01, and C_p^o = 40520 J/kmol K. T_r = 370.0/304.2 = 1.2163, and C_v = 40520 − 8314 = 32206 J/kmol K. Substituting in Eq. (2-128):

$$k_G = \frac{1.828 \times 10^{-5}}{44.01}\left[(1.30)\,(32206) + 14644.0 - \frac{2928.8}{1.2163}\right]$$

$$k_G = 0.02247 \text{ W/m K}$$

A value of 0.0220 W/m K is obtained from Vargaftik et al.[124]

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

For pure gases **above atmospheric pressure,** the method of Stiel and Thodos[102] may be used:

$$k_G = k'_G + \frac{A \times 10^{-4}(e^{B\rho_r} + C)}{\left(\frac{T_c^{1/6} M^{1/2}}{P_c^{2/3}}\right) Z_c^5} \tag{2-130}$$

$\rho_r < 0.5$	$A = 2.702$	$B = 0.535$	$C = -1.000$
$0.5 < \rho_r > 2.0$	$A = 2.528$	$B = 0.670$	$C = -1.069$
$2.0 < \rho_r > 2.8$	$A = 0.574$	$B = 1.155$	$C = 2.016$

where k_G = vapor thermal conductivity at the temperature T (K) and pressure P of interest, W/m K
k'_G = vapor thermal conductivity at T and atmospheric pressure, W/m K
ρ_r = reduced density = V_c/V
V_c = critical molar volume, m³/kmol
V = molar volume at T and P, m³/kmol
T_c = critical temperature, K
M = molecular weight
P_c = critical pressure, MPa
Z_c = critical compressibility factor = P_cV_c/RT_c
R = gas constant = 0.008314 MPa m³/kmol K

Errors in the range of 5–6 percent are typical with this method but may be higher for branched compounds.

Example 29 Estimate the thermal conductivity of carbon dioxide at 370 K and 10 MPa pressure. The required properties from Daubert et al.[24] are: T_c = 304.2 K, M = 44.01, P_c = 7.383 MPa, and V_c = 0.0940 m³/kmol; Z_c = (7.383) × (0.0940)/(0.008314)(304.2) = 0.274. k'_G = 0.0220 W/m K[123], and V = 0.22809 m³/kmol³; ρ_r = 0.0940/0.22809 = 0.4121. Substituting in Eq. (2-130) using the equation constants A, B, and C for $\rho_r < 0.5$:

$$k_G = 0.0220 + \frac{(2.702 \times 10^{-4})(e^{(0.535)(0.4121)} - 1.000)}{\left(\frac{(304.2)^{1/6}(44.01)^{1/2}}{(7.383)^{2/3}}\right)(0.274)^5} = 0.0315 \text{ W/m K}$$

Vargaftik et al.[124] report a value of 0.0308 W/m K.

The thermal conductivity of **low pressure** (1 atm or less) **gas mixtures** can be determined from the relation of Wassiljewa[126]:

$$k_m = \sum_{i=1}^{n} \frac{y_i k_i}{\sum_{j-1}^{n} y_j A_{ij}} \tag{2-131}$$

where k_m = mixture thermal conductivity, W/m K
n = number of components
$y_{i,j}$ = mole fraction of component i or j in the vapor mixture
k_i = thermal conductivity of pure component i at the temperature of interest

The binary interaction parameter A_{ij} is obtained by the method of Lindsay and Bromley[61]:

$$A_{ij} = \frac{1}{4}\left\{1 + \left[\frac{\mu_i}{\mu_j}\left(\frac{M_j}{M_i}\right)^{3/4}\left(\frac{T+S_i}{T+S_j}\right)\right]^{1/2}\right\}^2 \left(\frac{T+S_{ij}}{T+S_i}\right) \tag{2-132}$$

where $\mu_{i,j}$ = vapor viscosity of pure component i or j at the temperature T of interest and low pressure, Pa·s
$M_{i,j}$ = molecular weight of pure component i or j
T = temperature, K
$S_{ij} = S_{ji}$; see Eq. (2-133)
C = 1.0 except when either or both components i and j are very polar; then C = 0.73
$S_{i,j}$ = 79 K for helium, hydrogen, and neon; for all others, see Eq. (2-134)
$T_{bi,j}$ = normal boiling temperature of pure component i or j, K

$$S_{ji} = C(S_iS_j)^{1/2} \tag{2-133}$$

$$S_{i,j} = 1.5T_{bi,j} \tag{2-134}$$

Expected errors for this method are 4–5 percent. At **higher pressures,** a pressure correction using Eq. (2-130) may be used. The mixture is treated as a hypothetical pure component with mixture critical properties obtained via Eqs. (2-5), (2-8), and (2-17) and with the molecular weight being mole-averaged.

Example 30 Estimate thermal conductivity of a mixture of 0.23 mole fraction dimethylether (1) and 0.77 mole fraction methyl chloride (2) at 373.15 K and low pressure. The required pure component properties from Daubert et al.[24] are: k_1 = 0.02504 W/m K, k_2 = 0.01587 W/m K, μ_1 = 1.161 × 10⁻⁵ Pa·s, μ_2 = 1.361 × 10⁻⁵ Pa·s, M_1 = 46.07, M_2 = 50.49, T_{b1} = 248.3 K, and T_{b2} = 248.9 K. By Eq. (2-134), S_1 = (1.5)(248.3) = 372.45, and S_2 = (1.5)(248.9) = 373.35. By Eq. (2-133), $S_{12} = S_{21}$ = (1.0)[(372.45)(373.35)]^{1/2} = 372.90. Substituting in Eq. (2-132):

$$A_{11} = A_{22} = 1.0$$

$$A_{12} = \frac{1}{4}\left\{1 + \left[\left(\frac{1.161 \times 10^{-5}}{1.361 \times 10^{-5}}\right)\left(\frac{50.49}{46.07}\right)^{3/4}\left(\frac{373.15 + 372.45}{373.15 + 373.35}\right)\right]^{1/2}\right\}^2 \times \left(\frac{373.15 + 372.90}{373.15 + 372.45}\right) = 0.956$$

$$A_{21} = \frac{1}{4}\left\{1 + \left[\left(\frac{1.361 \times 10^{-5}}{1.161 \times 10^{-5}}\right)\left(\frac{46.07}{50.49}\right)^{3/4}\left(\frac{373.15 + 373.35}{373.15 + 372.45}\right)\right]^{1/2}\right\}^2 \times \left(\frac{373.15 + 372.90}{373.15 + 373.35}\right) = 1.047$$

Using Eq. (2-131):

$$k_m = \frac{(0.23)(0.02504)}{(0.23)(1.0) + (0.77)(0.956)} + \frac{(0.77)(0.01587)}{(0.23)(1.047) + (0.77)(1.0)} = 0.01805 \text{ W/m K}$$

The experimental value is 0.01778 W/m K.[66]

Liquids For **pure component hydrocarbon** liquids at reduced temperatures between 0.25 and 0.8 and at pressures below 3.4 MPa, an equation based on the methods of Pachaiyappan et al.[79] and Riedel[88] may be used:

$$k_L = C\rho M^n \left[\frac{3 + 20(1 - T_r)^{2/3}}{3 + 20\left(1 - \frac{293.15}{T_c}\right)^{2/3}}\right] \tag{2-135}$$

where k_L = liquid thermal conductivity, W/m K
M = molecular weight
ρ = molar density at 293.15 K, kmol/m³
T_r = reduced temperature, T/T_c
T = temperature, K
T_c = critical temperature, K

For unbranched, straight chain hydrocarbons, n = 1.001 and C = 1.811 × 10⁻⁴.

For branched and cyclic hydrocarbons, n = 0.7717 and C = 4.407 × 10⁻⁴.

Average errors are 5 percent when this equation is used. For pressures greater than 3.4 MPa, the thermal conductivity from Eq. (2-135) may be corrected by the technique suggested by Lenoir.[57] The correction factor is the ratio of conductivity factors F/F', where F is at the desired temperature and higher pressure, and F' is at the same temperature and lower pressure (usually atmospheric). The conductivity factors are calculated from:

$$F = 17.77 + 0.065P_r - 7.764T_r - \frac{2.054T_r^2}{e^{0.2P_r}} \tag{2-136}$$

where T_r = reduced temperature as in Eq. (2-135)
P_r = reduced pressure, P/P_c
P = pressure, MPa
P_c = critical pressure, MPa

The average error in the pressure correction alone is typically 3 percent.

Example 31 Estimate thermal conductivity of n-octane at 373.15 K and pressures of 0.1 MPa and 20.0 MPa. The required properties from Daubert et al.[24] are: ρ at 293.15 K = 6.155 kmol/m³, M = 114.2, T_c = 568.7 K, and P_c = 2.490 MPa. T_r = 373.15/568.7 = 0.6561, n = 1.001, and C = 1.811 × 10⁻⁴. Substituting in Eq. (2-135) for the thermal conductivity at 0.1 MPa:

$$k_L = (1.811 \times 10^{-4})(6.155)(114.2)^{1.001}\left[\frac{3 + (20)(1 - 0.6561)^{2/3}}{3 + (20)\left(1 - \frac{293.15}{568.7}\right)^{2/3}}\right]$$

$$= 0.107 \text{ W/m K}$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

The reported value is 0.111 W/m K.[123] To correct to 20 MPa, $P_r = 20.0/2.490 = 8.032$, and $P'_r = 0.1/2.490 = 0.04016$. Substituting in Eq. (2-136) to calculate F and F':

$$F = 17.77 + (0.065)(8.032) - (7.764)(0.6561) - \frac{(2.054)(0.6561)^2}{e^{(0.2)(8.032)}}$$

$$F = 13.02$$

$$F' = 17.77 + (0.065)(0.04016) - (7.764)(0.6561) - \frac{(2.054)(0.6561)^2}{e^{(0.2)(0.04016)}}$$

$$F' = 11.80$$

Thus, the thermal conductivity of n-octane at 373.15 K and 20.0 MPa is estimated to be (0.111)(13.02/11.80) = 0.122 W/m K as compared with an experimental value of 0.121 W/m K.[123]

For pure component hydrocarbon liquids **above the normal boiling point and all pressures,** the method of Kanitkar and Thodos[46] is recommended:

$$k_L = \frac{\alpha\, e^{\beta\rho_r}}{\lambda} \qquad P < 10{,}000 \text{ kPa} \qquad (2\text{-}137)$$

$$k_L = \frac{2.596 \times 10^{-4}\, P_r^{1.6} + \alpha\, e^{\beta\rho_r}}{\lambda} \qquad P > 10{,}000 \text{ kPa} \qquad (2\text{-}138)$$

where k_L = liquid thermal conductivity at the temperature T (K) and pressure P (kPa) of interest, W/m K

$$\alpha = 0.0112\, \beta^{-3.322} \qquad (2\text{-}139)$$

$$\beta = 0.40 + 0.986e^{-0.64\lambda} \qquad (2\text{-}140)$$

$$\lambda = T_c^{1/6} M^{1/2}\left(\frac{101.325}{P_c}\right)^{2/3} \qquad (2\text{-}141)$$

ρ_r = reduced density = V_c/V
V_c = critical molar volume, m³/kmol
V = molar volume at T and P, m³/kmol
T_c = critical temperature, K
M = molecular weight
P_c = critical pressure, kPa
P_r = reduced pressure, P/P_c

Average errors can be expected to be in the order of 10 percent.

Example 32 Estimate thermal conductivity of n-octane at 473.15 K and 15,000 kPa. The required properties from Daubert et al.[24] are: $T_c = 568.7$ K, $M = 114.2$, $P_c = 2490.0$ kPa, and $V_c = 0.4860$ m³/kmol. The specific volume at 473.15 K and 15,000 kPa is 0.001717 m³/kg[123]; $V = (0.001717)(114.2) = 0.1961$ m³/kmol. Thus, $P_r = 15000/2490 = 6.024$, and $\rho_r = 0.4860/0.1961 = 2.478$. Substituting in Eqs. (2-141), (2-140), and (2-139):

$$\lambda = (568.7)^{1/6}(114.2)^{1/2}\left(\frac{101.325}{2490}\right)^{2/3} = 3.639$$

$$\beta = 0.40 + 0.986e^{-(0.64)(3.639)} = 0.496$$

$$\alpha = (0.0112)(0.496)^{-3.322} = 0.115$$

Using Eq. (2-138):

$$k_L = \frac{(2.596 \times 10^{-4})(6.024)^{1.6} + 0.115e^{(0.496)(2.478)}}{3.639} = 0.109 \text{ W/m K}$$

The reported value is 0.106 W/m K.[123]

The thermal conductivity of **pure component nonhydrocarbon** liquids may be estimated by the method of Baroncini et al.,[5] with a modification by Myers[75] for silicon compounds, at reduced temperatures between 0.3 and 0.8 and at pressures below 3.5 MPa:

$$k_L = \left(\frac{abc}{m}\right)\left(\frac{(1 - T_r)^{0.38}}{T_r^{1/6}}\right) \qquad (2\text{-}142)$$

where k_L = liquid thermal conductivity, W/m K
T_r = reduced temperature, T/T_c
T = temperature, K
T_c = critical temperature, K
a = constant parameter
b = constant parameter = function of normal boiling temperature T_b, K
c = constant paramerer = function of critical temperature T_c, K
m = constant parameter = function of molecular weight M

Values of a, b, c, and m for various compound classes are found in Table 2-399. Average errors are about 8 percent.

Example 33 Estimate thermal conductivity of n-butanol. The properties required to estimate the liquid thermal conductivity of n-butanol at 360.0 K and 0.1 MPa from Daubert et al.[24] are: $T_c = 563.0$ K, $M = 74.12$, and T_b = 390.8 K. $T_r = 360.0/563.0 = 0.6394$. From Table 2-399, $a = 0.00339$, $b = (T_b)^{6/5} = (390.8)^{6/5} = 1289.3$, $c = (T_c)^{-1/6} = (563.0)^{-1/6} = 0.3480$, and $m = M^{1/2} = (74.12)^{1/2} = 8.609$. Substituting in Eq. (2-142):

$$k_L = \left[\frac{(0.00339)(1289.3)(0.3480)}{8.609}\right]\left[\frac{(1 - 0.6394)^{0.38}}{(0.6394)^{1/6}}\right] = 0.1292 \text{ W/m K}$$

The reported value is 0.1429 W/m K.[123]

TABLE 2-399 Values of Constant Parameters in Eq. (2-142) for Various Compound Classes

Compound class	a	b	c	m
Acids*	0.00319	$T_b^{6/5}$	$T_c^{-1/6}$	$M^{1/2}$
Alcohols, phenols	0.00339	$T_b^{6/5}$	$T_c^{-1/6}$	$M^{1/2}$
Esters†	0.0415	$T_b^{6/5}$	$T_c^{-1/6}$	M
Ethers	0.0385	$T_b^{6/5}$	$T_c^{-1/6}$	M
Halides‡	0.494	1.0	$T_c^{1/6}$	$M^{1/2}$
Refrigerants R20–R23	0.562	1.0	$T_c^{1/6}$	$M^{1/2}$
Ketones	0.00383	$T_b^{6/5}$	$T_c^{-1/6}$	$M^{1/2}$
Alkoxysilanes	0.00482	$T_b^{6/5}$	$T_c^{-1/6}$	$M^{1/2}$
Alkyl-(aryl)-chlorosilanes	0.6510	1.0	$T_c^{1/6}$	$M^{1/2}$

*Do not use for formic, myristic, or oleic acids.
†Do not use for butyl stearate.
‡Do not use for refrigerants R20–R23 ($CHCl_3$, $CHFCl_2$, $CHClF_2$, or CHF_3).

For pure component nonhydrocarbon liquids **for which Eq. (2-142) is not applicable,** the method of Missenard[72,73] may be used at temperature T (K) and below pressures of 3.5 MPa:

$$k_L = k_L^r\left[\frac{3 + 20\,(1 - T_r)^{2/3}}{3 + 20\left(1 - \dfrac{273.15}{T_c}\right)^{2/3}}\right] \qquad (2\text{-}143)$$

$$k_L^r = 2.656 \times 10^{-7}\,\frac{(T_b\rho^r)^{1/2}\, C_p^r}{M^{1/2}\, N^{1/4}} \qquad (2\text{-}144)$$

where k_L = liquid thermal conductivity, W/m K
k_L^r = liquid thermal conductivity at 273.15 K, W/m K
T_r = reduced temperature, T/T_c
T_c = critical temperature, K
T_b = normal boiling temperature, K
ρ^r = molar density at 273.15 K, kmol/m³
C_p^r = molar heat capacity at 273.15 K, J/kmol K
M = molecular weight
N = number of atoms in the molecule

Errors in the order of 8 percent can be expected.

Example 34 Estimate the thermal conductivity of n-propionaldehyde (CH_3CH_2CHO) at 318.15 K and low pressure (0.1 MPa); the necessary properties from Daubert et al.[24] are: $T_c = 504.4$ K, $T_b = 321.1$ K, $\rho^r = 14.11$ kmol/m³, $C_p^r = 1.309 \times 10^5$ J/kmol K, and $M = 58.08$. $N = 10$, and $T_r = 318.15/504.4 = 0.6307$. Substituting in Eq. (2-144):

$$k_L^r = (2.656 \times 10^{-7})\,\frac{[(321.1)\,(14.11)]^{1/2}\,(1.309 \times 10^5)}{(58.08)^{1/2}\,(10)^{1/4}} = 0.1727 \text{ W/m K}$$

Using Eq. (2-143):

$$k_L = 0.1727\left[\frac{3 + 20\,(1 - 0.6307)^{2/3}}{3 + 20\,(1 - 273.15/504.4)^{2/3}}\right] = 0.1542 \text{ W/m K}$$

A value from the literature is 0.1541 W/m K.[24]

For **pressures greater than 3.5 MPa,** the correction factor suggested by Missenard[74] may be used to obtain the thermal conductivity of pure component nonhydrocarbon liquids. Thus:

$$k_L = k'_L\left[0.98 + 0.0079\,P_r T_r^{1.4} + 0.63\,T_r^{1.2}\left(\frac{P_r}{30 + P_r}\right)\right] \qquad (2\text{-}145)$$

where k_L = liquid thermal conductivity at the desired temperature T (K) and pressure P (MPa), W/m K
k'_L = liquid thermal conductivity at T and pressure of 0.1 MPa, W/m K
P_r = reduced pressure, P/P_c
P_c = critical pressure, MPa
T_r = reduced temperature, T/T_c
T_c = critical temperature, K

Average errors are in the range of 5–20 percent.

Example 35 Estimate thermal conductivity of n-butanol. The required properties at 360 K and 15 MPa from Daubert et al.[24] are: $T_c = 563.0$ K and

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

P_c = 4.423 MPa. T_r = 360.0/563.0 = 0.6394 and P_r = 15.0/4.423 = 3.391. k'_L = 0.1429 W/m K.[123] Substituting in Eq. (2-145):

$$k_L = 0.1429\left[0.98 + (0.0079)\,(3.391)\,(0.6394)^{1.4} + (0.63)\,(0.6394)^{1.2}\left(\frac{3.391}{30 + 3.391}\right)\right]$$

$$= 0.1474 \text{ W/m K}$$

Vargaftik[123] reports a value of 0.1494 W/m K.

For both aqueous and nonaqueous **liquid mixtures,** the method of Li[59] is suggested for pressures below 3.5 MPa:

$$k_m = \sum_{i=1}^{n}\sum_{j=1}^{n} \phi_i\,\phi_j\,k_{ij} \tag{2-146}$$

$$\phi_i = \frac{x_i V_i}{\sum_{j=1}^{n} x_j V_j} \tag{2-147}$$

$$k_{ij} = \frac{2}{(1/k_i) + (1/k_j)} \tag{2-148}$$

where k_m = mixture liquid thermal conductivity at temperature T (K), W/m K
n = number of components
$x_{i,j}$ = mole fraction of component i or j in the liquid mixture
$V_{i,j}$ = liquid molar volume of pure component i or j at temperature T, m³/kmol
$k_{i,j}$ = liquid thermal conductivity of pure component i or j at temperature T, W/m K

Expected errors are in the 4–6 percent range. At **pressures greater than 3.5 MPa,** a pressure correction using Eq. (2-145) may be used. The mixture is treated as a hypothetical pure component with mixture critical properties obtained via Eqs. (2-5) and (2-8).

Example 36 Estimate thermal conductivity of a mixture of 0.302 mole fraction diethyl ether (1) and 0.698 mole fraction methanol (2) at 273.15 K and 0.1 MPa. The required properties from Daubert et al.[24] are: V_1 = 0.1007 m³/kmol, V_2 = 0.03942 m³/kmol, k_1 = 0.1383 W/m K, and k_2 = 0.2069 W/m K. Substituting in Eq. (2-148):

$$k_{12} = \frac{2}{1/0.1383 + 1/0.2069} = 0.1658$$

Then, using Eq. (2-147) to obtain ϕ_1 and ϕ_2:

$$\phi_1 = \frac{(0.302)(0.1007)}{(0.302)(0.1007) + (0.698)(0.03942)} = \frac{0.03041}{0.05793} = 0.525$$

$$\phi_2 = \frac{(0.698)(0.03942)}{0.05793} = 0.475$$

Substituting in Eq. (2-146):

$$k_m = (0.525)^2(0.1383) + 2(0.525)(0.475)(0.1658) + (0.475)^2(0.2069) = 0.167 \text{ W/m K}$$

Jamieson and Hastings[42] report a value of 0.173 W/m K for this mixture.

DIFFUSIVITY

Diffusion is the molecular transport of mass without flow. The diffusivity (D) or diffusion coefficient is the proportionality constant between the diffusion and the concentration gradient causing diffusion. It is usually defined by Fick's first law for one-dimensional, binary component diffusion for molecular transport without turbulence shown by Eq. (2-149)

$$\frac{N_1}{A} = -D_{12}\frac{dC_1}{dL} \tag{2-149}$$

The molar flow of species 1(N_1) per unit area (A) is directly proportional to the change in concentration of species 1 (C_1) per distance diffused (L). The usual units of diffusivity are m²/sec.

In chemical engineering, the primary application of the diffusivity is to calculate the Schmidt number ($\mu/\rho D$) used to correlate mass transfer properties. This number is also used in reaction rate calculations involving transport to and away from catalyst surfaces.

Experimental diffusion coefficients are scarce and not highly accurate, especially in the liquid phase, leading to prediction methods with marginal accuracy. However, use of the values predicted are generally suitable for engineering calculations. At concentrations above about 10 mole percent, predicted values should be used with caution. Diffusivities in liquids are 10^4–10^5 times lower than those in gases.

Gas Diffusivity For prediction of the gas diffusivity of **binary hydrocarbon-hydrocarbon gas systems at low pressures** (below about 500 psia [3.5 MPa]) the method of Gilliland[32] given by Eq. (2-150) is recommended.

$$D_{12} = \frac{0.1014T^{1.5}\left(\dfrac{1}{M_1} + \dfrac{1}{M_2}\right)^{0.5}}{P(V_1^{1/3} + V_2^{1/3})^2} \tag{2-150}$$

Component 1 is the solute, while component 2 is the solvent. Units of T, P, and V are °R, psia, and cm³/gmole, respectively. Diffusivity is then in ft²/hr. The molar volumes V_1 and V_2 at the normal boiling point are estimated by Tyn and Calus,[120] Eq. (2-151).

$$V_i = 0.285V_{c_i}^{1.048} \tag{2-151}$$

The method gives average errors of less than 4 percent.

For prediction of the gas diffusivity of **binary air-hydrocarbon or nonhydrocarbon gas mixtures at low pressures,** the method of Fuller et al.[30] given by Eq. (2-152) is recommended.

$$D_{12} = \frac{0.1013T^{1.75}\left(\dfrac{1}{M_1} + \dfrac{1}{M_2}\right)^{0.5}}{P[(\sum v_1)^{1/3} + (\sum v_2)^{1/3}]^2} \tag{2-152}$$

Units of T and P are K and Pa, respectively, with the resulting diffusivity in m²/sec. All v_i are group contribution values for the subscript component summed over atoms, groups, and structural features given in Table 2-400.

For air-hydrocarbon systems, average deviations do not exceed 9 percent. For general nonhydrocarbon gas systems, the average deviation is about 6 percent.

Example 37 Estimate the diffusivity of benzene vapor diffusing into air at 30°C and 96.5 kPa total pressure.

Use Eq. (2-152).

$$D_{12} = \frac{0.1013T^{1.75}\left(\dfrac{1}{M_1} + \dfrac{1}{M_2}\right)^{0.5}}{P[(\sum v_1)^{1/3} + (\sum v_2)^{1/3}]^2}$$

$$T = 303.1 \text{ K},\ M_1 = 78.1,\ M_2 = 28.86, \text{ and } P = 96{,}500 \text{ Pa}.$$

Now consult Table 2-400. For benzene (C_6H_6):

$$\sum v_1 = 6(16.5) + 6(1.98) - 20.2$$

$$\sum v_1 = 90.68$$

For air, $\sum v_2 = 20.1$:

$$D_{12} = \frac{(.01013)303.1^{1.75}\left(\dfrac{1}{78.1} + \dfrac{1}{28.86}\right)^{0.5}}{(96{,}500)(90.68^{1/3} + 20.1^{1/3})^2}$$

$$D_{12} = 9.68 \times 10^{-6} \text{ m}^2\text{/sec}$$

This value is within 1 percent of an available experimental value.

TABLE 2-400 Atomic Diffusion Volumes for Use in Eq. (2-153)

Atomic and structural diffusion-volume increments ν			
C	16.5	Cl	(19.5)
H	1.98	S	(17.0)
O	5.481	Aromatic ring	−20.2
N	(5.69)	Heterocyclic ring	−20.2
Diffusion volumes for simple molecules			
H_2	7.07	CO	18.9
D_2	6.70	CO_2	26.9
He	2.88	N_2O	35.9
N_2	17.9	NH_3	14.9
O_2	16.6	H_2O	12.7
Air	20.1	CCl_2F_2	(114.8)
Ar	16.1	SF_6	(69.7)
Kr	22.8	CI_2	(37.7)
Xe	(37.9)	Br_2	(67.2)
		SO_2	(41.1)

Parentheses indicate that the value listed is based only on a few data points.

TABLE 2-401 Parameters for Eq. (2-153)

P_r	$(D_{12}P)_R$	A	B	C	E
0.1	1.01	0.38042	1.52267	0.0	
0.2	1.01	0.067433	2.16794	0.0	
0.3	1.01	0.098371	2.42910	0.0	
0.4	1.01	0.137610	2.77605	0.0	
0.5	1.01	0.175081	2.98256	0.0	
0.6	1.01	0.216376	3.11384	0.0	
0.8	1.01	0.314051	0.50264	0.0	
1.0	1.02	0.385736	3.07773	0.141211	13.45454
1.2	1.02	0.514553	3.54744	0.278407	14.00000
1.4	1.02	0.599184	3.61216	0.372683	10.00900
1.6	1.02	0.557725	3.41882	0.504894	8.57519
1.8	1.03	0.593007	3.18415	0.678469	10.37483
2.0	1.03	0.696001	3.3760	0.0665702	11.21674
2.5	1.04	0.790770	3.27984	0.0	
3.0	1.05	0.502100	2.39031	0.602907	6.19043
4.0	1.06	0.837452	3.23513	0.0	
5.0	1.07	0.890390	3.13001	0.0	

An alternate method for gas diffusivity of binary gas mixtures at low pressures is the method of Hirschfelder et al.[40] The method requires several molecular parameters and, when evaluated, gives an average absolute error of about 10 percent. The method is discussed in detail in the *Data Prediction Manual.*

For predicting the diffusivity of *binary gas mixtures at high pressures,* the method of Takahashi,[109] Eq. (2-153), applies.

$$D_{12} = 1.013 \times 10^5 \frac{D'_{12}}{P}(D_{12}P)_R(1 - AT_r^{-B})(1 - CT_r^{-E}) \qquad (2\text{-}153)$$

D'_{12} is the low pressure diffusivity at the temperature of interest. $(D_{12}P)_R$ is a reduced diffusivity pressure product at infinite reduced temperature; and A, B, C, and E are constants. All are a function of P_r tabulated in Table 2-401. Component 1 is the diffusing species, while component 2 is the concentrated species. Critical properties are for the solvent. The pressure is given in Pa. The diffusivity is in m²/sec. Errors from evaluation average near 15 percent.

Example 38 Estimate the diffusivity of hydrogen (1) in nitrogen (2) at 60°C and 17.23 MPa. A value of the low pressure diffusivity obtained using Eq. (2-152) is $D'_{12} = 9.2 \times 10^{-5}$ m²/sec. Use Eq. (2-153):

$$D_{12} = 1.013 \times 10^5 \frac{D'_{12}}{P}(D_{12}P)_R(1 - AT_r^{-B})(1 - CT_r^{-E})$$

For nitrogen, $T_c = 126.2$ K and $P_c = 3.394$ MPa.

$$T_r = \frac{333.2}{126.2} = 2.640 \qquad P_r = \frac{17.23}{3.394} = 5.077$$

From Table 2-401:

$$(D_{12}P)_R = 1.07, \quad A = 0.89039, \quad B = 3.1300, \quad C = 0$$

$$D_{12} = 1.013 \times 10^5\left(\frac{9.2 \times 10^{-5}}{1.723 \times 10^7}\right)(1.07)[1 - .89039(2.64)^{-3.13}]$$

$$D_{12} = 5.54 \times 10^{-7} \text{ m}^2/\text{sec}$$

An available experimental value is 4.89×10^{-7} m²/sec.

For prediction of gas phase diffusion coefficients in **multicomponent hydrocarbon/nonhydrocarbon gas systems,** the method of Wilke[128] shown in Eq. (2-154) is used.

$$D_{im} = \frac{1 - y_i}{\sum_{j \neq 1}^{j} y_j / D_{ij}} \qquad (2\text{-}154)$$

This mixing rule is used to determine the diffusivity of any component in a $j + 1$ component mixture and requires binary diffusivities of component i with all other components. It has been estimated that errors are about 5 percent greater than the greatest error in the binary diffusivities. Fairbanks and Wilke,[28] using the same Eq. (2-154), made the same recommendation with essentially the same errors.

For prediction of the diffusivity of a **dilute dissolved gas (hydrocarbon or nonhydrocarbon) in a liquid,** the standard method is that of Wilke and Chang[129] shown by Eq. (2-155).

$$D_{12} = 1.1728 \times 10^{-16} \frac{T(\chi_2 M_2)^{1/2}}{\mu_2 V_1^{0.6}} \qquad (2\text{-}155)$$

Component 1 is the diffusing gas, while component 2 is the solvent. The solvent viscosity μ_2 in Pa sec, the solute molar volume at the normal boiling point V_1 in m³/kmole, and the solvent association parameter χ_2 multiplied by the solvent molecular weight are required input parameters. For the common solvents, χ decreases to 1 as polarity decreases, with values of 2.6 for water, 1.9 for methanol, 1.5 for ethanol, and 1.0 for less polar solvents. When tested with both hydrocarbon and nonhydrocarbon systems, average errors are about 25 percent—not excessive, considering the magnitude of the diffusivity.

Example 39 Estimate the infinite dilution diffusivity of propane (1) in chlorobenzene (2) at 25°C. Use Eq. (2-113):

$$D_{12} = 1.1728 \times 10^{-16} \frac{T(\chi_2 M_2)^{1/2}}{\mu_2 V_1^{0.6}}$$

For chlorobenzene, $M_2 = 112.56$, $\chi_2 = 1.0$, μ_2 @ 25°C $= 7.548 \times 10^{-4}$ Pa sec, and $V_1 = 0.0745$ m³/kmole.

$$D_{12} = \frac{(1.1728 \times 10^{-16})(298.15)(1.0 \times 112.56)^{1/2}}{(7.548 \times 10^{-4})(0.0745)^{0.6}}$$

$$D_{12} = 2.33 \times 10^{-9} \text{ m}^2/\text{sec}$$

An experimental value of 2.77×10^{-9} m²/sec is available.

Liquid Diffusivity Liquid diffusivities are in general not as accurately predicted as vapor diffusivities, and specialized methods have been developed. References to each method determined to be accurate are given, but only the most common methods will be presented.

For predicting liquid diffusivities of **binary nonpolar liquid systems at high solute dilution,** Umesi[120] developed a method that only depends on the viscosity of the solvent (2) and the radius of gyration of the solvent (2) and the solute (1). The *Technical Data Book—Petroleum Refining* gives the method and values of the radii of gyration for common hydrocarbons. Errors average 16 percent but reach 30 percent at times.

For predicting diffusivities in **binary polar or associating liquid systems at high solute dilution,** the method of Wilke and Chang[129] defined in Eq. (2-156) can be utilized. The Tyn and Calus equation (2-152) can be used to determine the molar volume of the solute at the normal boiling point. Errors average 20 percent, with occasional errors of 35 percent. The method is not considered to be accurate above a solute concentration of 5 mole percent.

For **concentrated binary nonpolar liquid systems** (more than 5 mole percent solute), the diffusivity can be estimated by a molar average mixing rule developed by Caldwell and Babb,[14] Eq. (2-156).

$$D_{1m} = x_1 D_{21} + (1 - x_1)D_{12} \qquad (2\text{-}156)$$

D_{21} and D_{12} are dilute solution binary diffusivities. Errors depend on the procedure used to determine the dilute solution diffusivities.

For **multicomponent nonpolar liquid systems,** Leffler and Cullinan[56] developed a mixing rule, Eq. (2-157).

$$D_{1m}\mu_m = (D_{12}\mu_2)^{x_2}(D_{13}\mu_3)^{x_3} \ldots \qquad (2\text{-}157)$$

The diffusivity of solute 1 in the mixture is related to the binary infinite dilution diffusivities for each of the other components calculated from Eq. (2-155) or the Umesi method. The viscosities are calculated by the methods in the previous section. Errors are not quantifiable, as little experimental data exist, although these errors would be related to those assumed for the binary pairs.

For **concentrated binary liquid nonhydrocarbon systems,** the method of Caldwell and Babb,[14] Eq. (2-156) has been modified by introduction of a thermodynamic correction term as shown in Eq. (2-158).

$$D_{1m}\mu_m = [x_i D_{21} + (1 - x_1)D_{12}]\left(1 + \frac{d \ln \gamma_1}{d \ln x_1}\right) \qquad (2\text{-}158)$$

The activity coefficient (γ) based corrector is calculated using any applicable activity correlating equation such as the van Laar (slightly polar) or Wilson (more polar) equations. The average absolute error is 20 percent.

An alternate method for **binary concentrated liquid systems** where activity coefficients are not available or estimable is the method of Leffler and Cullinan[56] previously given in Eq. (2-156). Absolute errors average 25 percent.

For estimating the diffusivity of the **dilute solute (10 mole percent) in water,** the method of Hayduk and Laudie,[37] Eq. (2-159), applies.

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

$$D_{12} = \frac{8.621 \times 10^{-14}}{\mu_2^{1.14} V_1^{0.589}} \qquad (2\text{-}159)$$

Component 1 is the solute, while component 2 is water. The molar volume of the solute in m^3/kmole is at the solute normal boiling point, while the viscosity of water in Pa sec is at the temperature of the system resulting in a diffusivity in m^2/sec. The average error is about 9 percent when tested on 36 experimental systems.

For estimating the diffusivity of a **dilute solute (<10 mole percent) in any solvent except water,** the method of King et al.,[49] Eq. (2-160), applies.

$$D_{12} = 4.4 \times 10^{-15} \, \frac{T}{\mu_2} \left(\frac{V_2}{V_1}\right)^{1/6} \left(\frac{\lambda_2}{\lambda_1}\right)^{1/2} \qquad (2\text{-}160)$$

Component 1 is the solute, while component 2 is the solvent. The latent heats, λ, are at the normal boiling point, as are the molar volumes. Using T in K and μ in Pa sec yields a diffusivity in m^2/sec. The average error is 21 percent when tested on 237 experimental systems.

For prediction of the **liquid diffusivity of a solute in a pair of mixed solvents,** the method of Tang and Himmelblau,[111] Eq. (2-161), is recommended.

$$\ln (D_{1m}\mu_m^{1/2}) = x_2 \ln (D_{12}^{*}\mu_2^{1/2}) + x_3 \ln (D_{13}^{*}\mu_3^{1/2}) \qquad (2\text{-}161)$$

The solute 1 is dissolved in a solvent pair of 2 and 3. D^* are infinite dilution binary diffusivities estimated by the proper method discussed previously. The mixture viscosity can be predicted by methods of the previous section. The average absolute error when tested on 40 systems is 25 percent. The method gives higher errors if the solute is gaseous.

SURFACE TENSION

The molecules in a gas-liquid interface are in tension and tend to contract to a minimum surface area. This tension may be quantified by the surface tension, which is defined as the force in the plane of the surface per unit length. Jasper[43] has made a critical evaluation of experimental surface tension data for approximately 2200 pure chemicals. He correlates surface tension σ (mN/m = dyn/cm) with temperature T (°C) over a specified temperature range as

$$\sigma = a - bT \qquad (2\text{-}162)$$

where a and b are listed for most of the substances. To obtain values at a higher temperature than the upper temperature limit indicated by Jasper, the following expression may be used:

$$\sigma = d(1 - T_r)^e \qquad (2\text{-}163)$$

where d and e are determined such that σ and $d\sigma/dT$ at the upper temperature limit T_{HI} have the same values when calculated from both Eqs. (2-162) and (2-163):

$$e = \frac{b(T_c - T_{HI})}{a - b\,T_{HI}} \qquad (2\text{-}164)$$

$$d = (a - b\,T_{HI})(1 - T_{HI})^{-e} \qquad (2\text{-}165)$$

where T_c = critical temperature, °C
T_r = reduced temperature = $(T + 273.15)/(T_c + 273.15)$

Eq. (2-163) correctly predicts that the surface tension becomes zero at the critical point.[87]

For **nonpolar, nonhydrocarbon** chemicals not found in Jasper,[43] use can be made of the corresponding states approach of Brock and Bird[9] as modified by Miller[69] at temperature T (K):

$$\sigma = 4.601 \times 10^{-4}\, P_c^{2/3}\, T_c^{1/3}\, Q\, (1 - T_r)^{11/9} \qquad (2\text{-}166)$$

$$Q = 0.1207 \left[1 + \frac{T_{br}(\ln P_c - 11.5261)}{1 - T_{br}}\right] - 0.281 \qquad (2\text{-}167)$$

where σ = surface tension, mN/m
P_c = critical pressure, Pa
T_c = critical temperature, K
T_r = reduced temperature, T/T_c
T_b = normal boiling temperature, K
T_{br} = reduced normal boiling temperature, T_b/T_c

Errors are usually less than 5 percent.

Example 40 Estimate surface tension for ethyl mercaptan. The required properties from Daubert et al.[24] are $P_c = 5.49 \times 10^6$ Pa, $T_c = 499.15$ K, and $T_b = 308.15$ K. For $T = 303.15$ K, $T_r = 303.15/499.15 = 0.6073$, and $T_{br} = 308.15/499.15 = 0.6173$. Substituting into Eqs. (2-167) and (2-166):

$$Q = 0.1207 \left[1 + \frac{0.6173\,(\ln 5.49 \times 10^6 - 11.5261)}{1 - 0.6173}\right] - 0.281$$

$$Q = 0.6170$$

$$\sigma = 4.601 \times 10^{-4}(5.49 \times 10^6)^{2/3}(499.15)^{1/3}(0.6170)(1 - 0.6073)^{11/9}$$

$$\sigma = 22.36 \text{ mN/m}$$

The reported experimental value is 22.68 mN/m.[43]

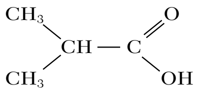
For **hydrocarbon and polar** chemicals, the approach originally suggested by Macleod[65] as further developed by Sugden[106,107] can be used:

$$\sigma = \left\{\frac{[P]}{1000}\,(\rho_L - \rho_G)\right\}^4 \qquad (2\text{-}168)$$

where σ = surface tension, mN/m
ρ_L = liquid density, kmol/m^3
ρ_G = vapor density, kmol/m^3

The temperature-independent parachor [P] may be calculated by the additive scheme proposed by Quale.[83] The atomic group contributions for this method, with contributions for silicon, boron, and aluminum from Myers,[75] are shown in Table 2-402. At low pressures, where $\rho_L >> \rho_G$, the vapor density term may be neglected. Errors using Eq. (2-168) are normally less than 5 to 10 percent.

Example 41 Estimate surface tension for isobutyric acid. For isobutyric acid, the liquid density from Daubert et al.[24] is 10.77 kmol/m^3 at 293.15 K. [P] is determined from Table 2-402:



is made up of the two groups CH_3—$CH(CH_3)$— and —COOH. Therefore, $[P] = 133.3 + 73.8 = 207.1$. With Eq. (2-168), neglecting the vapor density,

$$\sigma = \left[\frac{207.1}{1000}\,(10.77)\right]^4 = 24.75 \text{ mN/m}$$

Jasper[43] quotes a value of 25.04 mN/m at 293.15 K.

In general, the surface tension of a **liquid mixture** is not a simple function of the pure component surface tensions because the composition of the mixture surface is not the same as the bulk. For **nonaqueous** solutions of n components, the method of Winterfeld, Scriven, and Davis[130] is applicable:

$$\sigma_m = \sum_{i=1}^{n} \sum_{j=1}^{n} \rho^2 \left(\frac{x_i}{\rho_{Li}}\right)\left(\frac{x_i}{\rho_{Li}}\right)(\sigma_i\sigma_j)^{1/2} \qquad (2\text{-}169)$$

$$\frac{1}{\rho} = \sum_{i=1}^{n} \frac{x_i}{\rho_{Li}} \qquad (2\text{-}170)$$

where σ_m = mixture surface tension, mN/m
$x_{i,j}$ = mole fraction of component i or j in the liquid mixture
$\rho_{Li,j}$ = pure component liquid density of component i or j, kmol/m^3
$\sigma_{i,j}$ = pure component surface tension of component i or j, mN/m

Accuracies of 3–4 percent average deviation are typical when using this method.

Example 42 Estimate surface tension of a mixture. At 298.15 K, Daubert et al.[24] report the liquid density of n-pentane to be 8.617 kmol/m^3 and its surface tension to be 15.47 mN/m. From the same source, the corresponding values for dichloromethane are 15.52 kmol/m^3 and 27.22 mN/m. Using Eqs. (2-170) and (2-169) for a mixture of 0.1606 mole fraction n-pentane and 0.8394 mole fraction dichloromethane:

$$\frac{1}{\rho} = \frac{0.1606}{8.617} + \frac{0.8394}{15.52}$$

$$\rho = 13.75 \text{ kmol/m}^3$$

TABLE 2-402 Atomic Group Contributions for Calculation of the Parachor [P]

Atomic group	[P]	Atomic group	[P]
Carbon-hydrogen		**Special Groups (*Cont.*)**	
C	9.0	B	13.2
H	15.5	Al	34.9
CH_3—	55.5	F	26.1
$(—CH_2—)_n$		Cl	55.2
$n = 1 - 12$	40.0	Br	68.0
$n > 12$	40.3	I	90.3
$CH_3—CH(CH_3)—$	133.3		
$CH_3—CH_2—CH(CH_3)—$	171.9	**Ethylenic Bond**	
$CH_3—CH_2—CH_2—CH(CH_3)—$	211.7	Terminal*	19.1
$CH_3—CH(CH_3)—CH_2—$	173.3	2,3-position	17.7
$CH_3—CH_2—CH(C_2H_5)—$	209.5	3,4-position†	16.3
$CH_3—C(CH_3)_2—$	170.4		
$CH_3—CH_2—C(CH_3)_2—$	207.5	**Triple Bond**	40.6
$CH_3—CH(CH_3)—CH(CH_3)—$	207.9		
$CH_3—CH(CH_3)—C(CH_3)_2—$	243.5	**Ring Closure**	
$C_6H_5—$	189.6	3-membered	12.5
		4-membered	6.0
Special Groups		5-membered	3.0
H in OH	10.0	6-membered	0.8
H in HN	12.5	7-membered	4.0
O	19.8		
—OH	29.8	**=0 (ketone)**	
O_2 in acids, esters	54.8	3 carbon atoms	22.3
—COO—	63.8	4 carbon atoms	20.0
—COOH	73.8	5 carbon atoms	18.5
N	17.5	6 carbon atoms	17.3
$—NH_2$	42.5	7 carbon atoms	17.3
S	49.1	8 carbon atoms	15.1
P	40.5	9 carbon atoms	14.1
Si	30.3	10 carbon atoms	13.0
Si (silanes)	43.3	11 carbon atoms	12.6

*Use the value for double bonds in cyclic compound. Assume 3 double bonds for the aromatic ring.
†Use 16.3 for double bonds in the 3, 4 or higher positions.

$$\sigma_m = (13.75)^2 \left(\frac{0.1606}{8.617}\right)^2 (15.47) + 2(13.75)^2 \left(\frac{0.1606}{8.617}\right)\left(\frac{0.8394}{15.52}\right)[(15.47)(27.22)]^{1/2} + (13.75)^2 \left(\frac{0.8394}{15.52}\right)^2 (27.22)$$

$$\sigma_m = 23.89 \text{ mN/m}$$

De Soria et al.[26] give an experimental value of 24.24 mN/m for this mixture.

Surface tensions for **aqueous** solutions are more difficult to predict than those for nonaqueous mixtures because of the nonlinear dependence on mole fraction. Small concentrations of the organic material may significantly affect the mixture surface tension value. For many binary organic-water mixtures, the method of Tamura, Kurata, and Odani[110] may be used:

$$\sigma_m^{1/4} = \psi_w \sigma_w^{1/4} + \psi_o \sigma_o^{1/4} \qquad (2\text{-}171)$$

where σ_m = mixture surface tension, mN/m
σ_w = surface tension of pure water, mN/m
σ_o = surface tension of pure organic component, mN/m

$$\psi_o = 1 - \psi_w \qquad (2\text{-}172)$$

ψ_w is defined by the relation:

$$\log_{10} \frac{(\psi_w)^q}{(1-\psi_w)} = \log_{10}\left[\frac{(x_w V_w)^q}{x_o V_o}(x_w V_w + x_o V_o)^{1-q}\right] + 44.1 \frac{q}{T}\left[\frac{\sigma_o V_o^{2/3}}{q} - \sigma_w V_w^{2/3}\right] \qquad (2\text{-}173)$$

where x_w = bulk mole fraction of pure water
x_o = bulk mole fraction of pure organic component
V_w = molar volume of pure water, m^3/kmol
V_o = molar volume of pure organic component, m^3/kmol
T = temperature, K
q = constant depending upon the size and type of the organic component; see table:

Organic component	q	Example
Fatty acids, alcohols	Number of carbon atoms	Acetic acid: $q = 2$
Ketones	One less than the number of carbon atoms	Acetone: $q = 2$
Halogen derivatives of fatty acids	Number of carbon atoms times the ratio of the molar volume of the halogen derivative to the parent fatty acid	Chloroacetic acid
		$q = 2 \dfrac{V(\text{chloroacetic acid})}{V(\text{acetic acid})}$

Expected errors are less than 10 percent when q is less than 5 and within 20 percent when q is greater than 5.

Example 43 Estimate surface tension of a water-methanol mixture. Equation (2-171) can be used with a water-methanol mixture at 303.15 K when the methanol mole fraction is 0.122. From Jasper,[43] σ_w = 71.40 mN/m, and σ_o = 21.73 mN/m. The density of water (per Ref. 24) is 55.16 kmol/m^3; V_w = 0.01813 m^3/kmol. The density of methanol is 24.49 kmol/m^3 (Ref. 24); V_o = 0.04083 m^3/kmol. For methanol, $q = 1$. Using Eq. (2-173) to obtain ψ_w:

$$\log_{10}\frac{\psi_w}{1-\psi_w} = \log_{10}\left[\frac{(0.878)(0.01813)}{(0.122)(0.04083)}\right] + \frac{44.1}{303.15}[(21.73)(0.04083)^{2/3} - (71.40)(0.01813)^{2/3}]$$

$$= 0.505 - 0.342 = 0.163$$

$$\frac{\psi_w}{1-\psi_w} = 10^{0.163} = 1.455$$

$$\psi_w = \frac{1.455}{2.455} = 0.593$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Using Eq. (2-172): $\psi_o = 1 - 0.593 = 0.407$. Substituting into Eq. (2-171):

$$\sigma_m^{1/4} = (0.593)(71.40)^{1/4} + (0.407)(21.73)^{1/4}$$

$$\sigma_m^{1/4} = 2.603$$

$$\sigma_m = 45.91 \text{ mN/m}$$

The reported experimental value is 46.1 mN/m.[110]

FLAMMABILITY PROPERTIES

Flash points, lower and upper flammability limits, and autoignition temperatures are the three properties used to indicate safe operating limits of temperature when processing organic materials. Prediction methods are somewhat erratic, but, together with comparisons with reliable experimental values for families or similar compounds, they are valuable in setting a conservative value for each of the properties. The DIPPR compilation includes evaluated values for over 1000 common organics. Detailed examples of most of the methods discussed are available in Danner and Daubert.[22]

The flash point is the lowest temperature at which a liquid gives off sufficient vapor to form an ignitable mixture with air near the surface of the liquid or within the vessel used. ASTM test methods include procedures using a closed cup (ASTM D56, ASTM D93, and ASTM D3828), which is preferred, and an open cup (ASTM D92 and ASTM D1310). When several values are available, the *lowest* temperature is usually taken in order to assure safe operation of the process.

The method of Shebeko et al.[96] is the preferred flash point prediction method. The formula of the compound, the system pressure, and vapor pressure data for the compound must be available or estimable. Equation (2-174) is the basic equation.

$$P^{\text{sat}} = \frac{P}{1 + 4.76(2\beta - 1)} = 0 \qquad (2\text{-}174)$$

$$\beta = N_C + N_S + \frac{(N_H - N_X)}{4} - \frac{N_O}{2}$$

N's are the numbers of **atoms** of carbon (C), sulfur (S), hydrogen (H), halogens (X), and oxygen (O) in the molecule. P is the total system pressure. P^{sat} is the vapor pressure of the compound at the flash point temperature.

If P^{sat} is available as a function of temperature, Eq. (2-174) can be solved directly for the flash point temperature. Otherwise, trial and error with a table of P^{sat} vs. T is required. Errors average about 5°C but may be as much as 15°C.

An alternate method for flash point prediction is the method of Gmehling and Rasmussen[33] and depends on the lower flammability limit (discussed later). Vapor pressure as a function of temperature is also required. The method is generally not as accurate as the preceding method as flammability limit errors are propagated. The authors have also extended the method to defined mixtures of organics.

The upper and lower flammability limits are the boundary-line mixtures of vapor or gas with air, which, if ignited, will just propagate flame and are given in terms of percent by volume of gas or vapor in the air. Each of these limits also has a temperature at which the flammability limits are reached. The temperature corresponding to the lower-limit partial vapor pressure should equal the flash point. The temperature corresponding to the upper-limit partial vapor pressure is somewhat above the lower limit and is usually considerably below the autoignition temperature. Flammability limits are calculated at one atmosphere total pressure and normally are considered synonymous with explosive limits. Limits in oxygen rather than air are sometimes measured and available. Limits are generally reported at 298 K and 1 atm. If temperature or pressure are increased, the lower limit will decrease while the upper limit will increase, giving a wider range of compositions over which flame will propagate.

The most generally applicable method for prediction of the property is the method of Seaton,[95] which depends only on the molecular structure of the molecule and utilizes second order (Benson-type) groups to construct the molecule. Equation (2-175) sums the groups' number of each type group (n_i) to get both the upper and lower limits.

$$z_u \quad \text{or} \quad z_l = \frac{\sum (n_i f_i)}{\sum \left(\frac{n_i f_i}{g_i}\right)} \qquad (2\text{-}175)$$

Two sets of f_i and g_i are given in the article for each second-order group to cover both upper (u) and lower (l) limits (z) in volume percent units. A study of this method for about 80 organic compounds in 14 families shows absolute errors of 0.15 percent and 2.3 percent for the lower and upper limits, respectively. The upper limit prediction should not be used for ethers.

Alternate group contribution methods dependent only on molecular structure are the method of Shebeko et al.[97] modified by High and Siegel[39] for lower flammability limit and the method of High and Danner[38] for upper flammability limit. Both methods are detailed by Danner and Daubert.[22] A study comparing these methods with the Seaton method shows slightly higher absolute errors of 0.23 percent and 2.9 percent for the lower and upper limits, respectively. The upper limit prediction should not be used for ethers. Both methods are recommended to be used only for qualitative guidance. Lower flammability limits can also be back-calculated from a known flash point by the method of Gmehling and Rasmussen[33] discussed earlier.

The autoignition temperature is the minimum temperature for a substance to initiate self-combustion in air in the absence of a spark or flame. The temperature is no lower than and is generally considerably higher than the temperature corresponding to the upper flammability limit. Large differences can occur in reported values determined by different procedures. The lowest reasonable value should be accepted in order to assure safety. Values are also sometimes given in oxygen rather than in air.

Values for hydrocarbons other than alkynes and alkadienes can be predicted by the method of Suzuki et al.[108] The best model includes the descriptors T_c, P_c, the parachor, the molecular surface area (which can be approximated by the van der Waals area), and the zero-order connectivity index. Excluding alkynes and alkadienes, a study for 58 alkanes, aromatics, and cycloalkanes showed an average deviation from experimental values of about 30 K.

Another method of estimating autoignition temperatures is to compare values for a compound with other members of its homologous series on a plot vs. carbon number as the temperature decreases and carbon number increases. Affens[1] gives a formal procedure for such estimation.

MATHEMATICS

GENERAL

The basic problems of the sciences and engineering fall broadly into three categories:

1. *Steady state problems.* In such problems the configuration of the system is to be determined. This solution does not change with time but continues indefinitely in the same pattern, hence the name "steady state." Typical chemical engineering examples include steady temperature distributions in heat conduction, equilibrium in chemical reactions, and steady diffusion problems.

2. *Eigenvalue problems.* These are extensions of equilibrium problems in which critical values of certain parameters are to be determined in addition to the corresponding steady-state configurations. The determination of eigenvalues may also arise in propagation problems. Typical chemical engineering problems include those in heat transfer and resonance in which certain boundary conditions are prescribed.

3. *Propagation problems.* These problems are concerned with predicting the subsequent behavior of a system from a knowledge of the initial state. For this reason they are often called the transient (time-varying) or unsteady-state phenomena. Chemical engineering examples include the transient state of chemical reactions (kinetics), the propagation of pressure waves in a fluid, transient behavior of an adsorption column, and the rate of approach to equilibrium of a packed distillation column.

The mathematical treatment of engineering problems involves four basic steps:

1. *Formulation.* The expression of the problem in mathematical language. That translation is based on the appropriate physical laws governing the process.

2. *Solution.* Appropriate mathematical operations are accomplished so that logical deductions may be drawn from the mathematical model.

3. *Interpretation.* Development of relations between the mathematical results and their meaning in the physical world.

4. *Refinement.* The recycling of the procedure to obtain better predictions as indicated by experimental checks.

Steps 1 and 2 are of primary interest here. The actual details are left to the various subsections, and only general approaches will be discussed.

The formulation step may result in algebraic equations, difference equations, differential equations, integral equations, or combinations of these. In any event these mathematical models usually arise from statements of physical laws such as the laws of mass and energy conservation in the form.

Input of conserved quantity − output of conserved quantity
+ conserved quantity produced
= accumulation of conserved quantity

Rate of input of conserved quantity − rate of output of
conserved quantity + rate of conserved quantity produced
= rate of accumulation of conserved quantity

These statements may be abbreviated by the statement

Input − output + production = accumulation

When the basic physical laws are expressed in this form, the formulation is greatly facilitated. These expressions are quite often given the names, "material balance," "energy balance," and so forth. To be a little more specific, one could write the law of conservation of energy in the steady state as

Rate of energy in − rate of energy out + rate of energy produced = 0

Many general laws of the physical universe are expressible by differential equations. Specific phenomena are then singled out from the infinity of solutions of these equations by assigning the individual initial or boundary conditions which characterize the given problem. In mathematical language one such problem, the equilibrium problem, is called a boundary-value problem (Fig. 3-1). Schematically, the problem is characterized by a differential equation plus an open region in which the equation holds and, on the boundaries of the region, by certain conditions (boundary conditions) that are dictated by the physical problem. The solution of the equation must satisfy the differential equation inside the region and the prescribed conditions on the boundary.

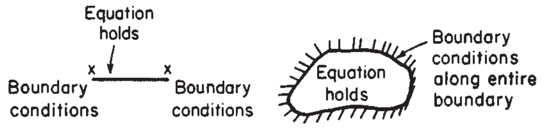

FIG. 3-1 Boundary conditions.

In mathematical language, the propagation problem is known as an initial-value problem (Fig. 3-2). Schematically, the problem is characterized by a differential equation plus an open region in which the equation holds. The solution of the differential equation must satisfy the initial conditions plus any "side" boundary conditions.

The description of phenomena in a "continuous" medium such as a gas or a fluid often leads to partial differential equations. In particular, phenomena of "wave" propagation are described by a class of partial differential equations called "hyperbolic," and these are essentially different in their properties from other classes such as those that describe equilibrium ("elliptic") or diffusion and heat transfer ("parabolic"). Prototypes are:

1. *Elliptic.* Laplace's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

Poisson's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = g(x,y)$$

These do not contain the variable t (time) explicitly; accordingly, their solutions represent equilibrium configurations. Laplace's equation corresponds to a "natural" equilibrium, while Poisson's equation corresponds to an equilibrium under the influence of an external force of density proportional to $g(x, y)$.

2. *Parabolic.* The heat equation

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}$$

describes nonequilibrium or propagation states of diffusion as well as heat transfer.

3. *Hyperbolic.* The wave equation

$$\frac{\partial^2 u}{\partial t^2} = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}$$

describes wave propagation of all types when the assumption is made that the wave amplitude is small and that interactions are linear.

The solution phase has been characterized in the past by a concentration on methods to obtain analytic solutions to the mathematical

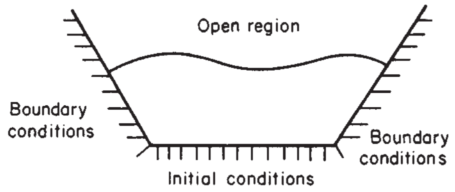

FIG. 3-2 Propagation problem.

equations. These efforts have been most fruitful in the area of the linear equations such as those just given. However, many natural phenomena are nonlinear. While there are a few nonlinear problems that can be solved analytically, most cannot. In those cases, numerical methods are used. Due to the widespread availability of software for computers, the engineer has quite good tools available.

Numerical methods almost never fail to provide an answer to any particular situation, but they can never furnish a general solution of any problem.

The mathematical details outlined here include both analytic and numerical techniques useful in obtaining solutions to problems.

Our discussion to this point has been confined to those areas in which the governing laws are well known. However, in many areas, information on the governing laws is lacking. Interest in the application of statistical methods to all types of problems has grown rapidly since World War II. Broadly speaking, statistical methods may be of use whenever conclusions are to be drawn or decisions made on the basis of experimental evidence. Since statistics could be defined as the technology of the scientific method, it is primarily concerned with the first two aspects of the method, namely, the performance of experiments and the drawing of conclusions from experiments. Traditionally the field is divided into two areas:

1. *Design of experiments.* When conclusions are to be drawn or decisions made on the basis of experimental evidence, statistical techniques are most useful when experimental data are subject to errors. The design of experiments may then often be carried out in such a fashion as to avoid some of the sources of experimental error and make the necessary allowances for that portion which is unavoidable. Second, the results can be presented in terms of probability statements which express the reliability of the results. Third, a statistical approach frequently forces a more thorough evaluation of the experimental aims and leads to a more definitive experiment than would otherwise have been performed.

2. *Statistical inference.* The broad problem of statistical inference is to provide measures of the uncertainty of conclusions drawn from experimental data. This area uses the theory of probability, enabling scientists to assess the reliability of their conclusions in terms of probability statements.

Both of these areas, the mathematical and the statistical, are intimately intertwined when applied to any given situation. The methods of one are often combined with the other. And both in order to be successfully used must result in the numerical answer to a problem—that is, they constitute the means to an end. Increasingly the numerical answer is being obtained from the mathematics with the aid of computers.

MISCELLANEOUS MATHEMATICAL CONSTANTS

Numerical values of the constants that follow are approximate to the number of significant digits given.

$\pi = 3.1415926536$	Pi
$e = 2.7182818285$	Napierian (natural) logarithm base
$\gamma = 0.5772156649$	Euler's constant
$\ln \pi = 1.1447298858$	Napierian (natural) logarithm of pi, base e
$\log \pi = 0.4971498727$	Briggsian (common logarithm of pi, base 10
Radian = 57.2957795131°	
Degree = 0.0174532925 rad	
Minute = 0.0002908882 rad	
Second = 0.0000048481 rad	

THE REAL-NUMBER SYSTEM

The natural numbers, or counting numbers, are the positive integers: 1, 2, 3, 4, 5, ... The negative integers are −1, −2, −3, ...

A number in the form a/b, where a and b are integers, $b \neq 0$, is a rational number. A real number that cannot be written as the quotient of two integers is called an irrational number, e.g., $\sqrt{2}$, $\sqrt{3}$, $\sqrt{5}$, π, e, $\sqrt[3]{2}$.

There is a one-to-one correspondence between the set of real numbers and the set of points on an infinite line (coordinate line).

Order among Real Numbers; Inequalities

$a > b$ means that $a - b$ is a positive real number.
If $a < b$ and $b < c$, then $a < c$.
If $a < b$, then $a \pm c < b \pm c$ for any real number c.
If $a < b$ and $c > 0$, then $ac < bc$.
If $a < b$ and $c < 0$, then $ac > bc$.
If $a < b$ and $c < d$, then $a + c < b + d$.
If $0 < a < b$ and $0 < c < d$, then $ac < bd$.
If $a < b$ and $ab > 0$, then $1/a > 1/b$.
If $a < b$ and $ab < 0$, then $1/a < 1/b$.

Absolute Value For any real number x, $|x| = \begin{cases} x & \text{if } x \geq 0 \\ -x & \text{if } x < 0 \end{cases}$

Properties

If $|x| = a$, where $a > 0$, then $x = a$ or $x = -a$.
$|x| = |-x|$; $-|x| \leq x \leq |x|$; $|xy| = |x|\,|y|$.
If $|x| < c$, then $-c < x < c$, where $c > 0$.
$||x| - |y|| \leq |x + y| \leq |x| + |y|$.
$\sqrt{x^2} = |x|$.

Proportions If $\dfrac{a}{b} = \dfrac{c}{d}$, then $\dfrac{a+b}{b} = \dfrac{c+d}{d}$, $\dfrac{a-b}{b} = \dfrac{c-d}{d}$, $\dfrac{a-b}{a+b} = \dfrac{c-d}{c+d}$.

Indeterminants

Form	Example	
$(\infty)(0)$	xe^{-x}	$x \to \infty$
0^0	x^x	$x \to 0^+$
∞^0	$(\tan x)^{\cos x}$	$x \to \frac{1}{2}\pi^-$
1^∞	$(1 + x)^{1/x}$	$x \to 0^+$
$\infty - \infty$	$\sqrt{x+1} - \sqrt{x-1}$	$x \to \infty$
$\frac{0}{0}$	$\frac{\sin x}{x}$	$x \to 0$
$\frac{\infty}{\infty}$	$\frac{e^x}{x}$	$x \to \infty$

Limits of the type $0/\infty$, $\infty/0$, 0^∞, $\infty \cdot \infty$, $(+\infty) + (+\infty)$, and $(-\infty) + (-\infty)$ are *not* indeterminate forms.

Integral Exponents (Powers and Roots) If m and n are positive integers and a, b are numbers or functions, then the following properties hold:

$$a^{-n} = 1/a^n \qquad a \neq 0$$
$$(ab)^n = a^n b^n$$
$$(a^n)^m = a^{nm}, \qquad a^n a^m = a^{n+m}$$
$$\sqrt[n]{a} = a^{1/n} \quad \text{if} \quad a > 0$$
$$\sqrt[m]{\sqrt[n]{a}} = \sqrt[mn]{a}, \; a > 0$$
$$a^{m/n} = (a^m)^{1/n} = \sqrt[n]{a^m}, \; a > 0$$
$$a^0 = 1 \; (a \neq 0)$$
$$0^a = 0 \; (a \neq 0)$$

Infinity (∞) is not a real number. It is possible to extend the real-number system by adjointing to it "∞" and "$-\infty$," and within the extended system, certain operations involving $+\infty$ or $-\infty$ are possible. For example, if $0 < a < 1$, then $a^\infty = \lim_{x\to\infty} a^x = 0$, whereas if $a > 1$, then $a^\infty = \infty$, $\infty^a = \infty$ $(a > 0)$, $\infty^a = 0$ $(a < 0)$.

Care should be taken in the case of roots and fractional powers of a product; e.g., $\sqrt{xy} \neq \sqrt{x}\sqrt{y}$ if x and y are negative. This rule applies if one is careful about the domain of the functions involved; so $\sqrt{xy} = \sqrt{x}\sqrt{y}$ if $x > 0$ and $y > 0$.

Given any number $b > 0$, there is a unique function $f(x)$ defined for all real numbers x such that (1) $f(x) = b^x$ for all rational x; (2) f is increasing if $b > 1$, constant if $b = 1$, and decreasing if $0 < b < 1$. This function is called the exponential function b^x. For any $b > 0$, $f(x) = b^x$ is

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

a continuous function. Also with $a,b > 0$ and x,y any real numbers, we have

$$(ab)^x = a^x b^x$$
$$b^x b^y = b^{x+y}$$
$$(b^x)^y = b^{xy}$$

The exponential function with base b can also be defined as the inverse of the logarithmic function. The most common exponential function in applications corresponds to choosing b the transcendental number e.

Logarithms $\log ab = \log a + \log b$, $a > 0, b > 0$

$$\log a^n = n \log a$$
$$\log (a/b) = \log a - \log b$$
$$\log \sqrt[n]{a} = (1/n) \log a$$

The common logarithm (base 10) is denoted $\log a$ or $\log_{10} a$. The natural logarithm (base e) is denoted $\ln a$ (or in some texts $\log_e a$).

Roots If a is a real number, n is a positive integer, then x is called the nth root of a if $x^n = a$. The number of nth roots is n, but not all of them are necessarily real. The principal nth root means the following: (1) if $a > 0$ the principal nth root is the unique positive root, (2) if $a < 0$, and n odd, it is the unique negative root, and (3) if $a < 0$ and n even, it is any of the complex roots. In cases (1) and (2), the root can be found on a calculator by taking $y = \ln a/n$ and then $x = e^y$. In case (3), see the section on complex variables.

PROGRESSIONS

Arithmetic Progression

$$\sum_{k=0}^{n-1} (a + kd) = na + \frac{1}{2} n(n-1)d = \frac{n}{2}(a + \ell)$$

where ℓ is the last term, $\ell = a + (n-1)d$.

Geometric Progression

$$\sum_{k=1}^{n} ar^{k-1} = \frac{a(r^n - 1)}{r - 1} \qquad (r \neq 1)$$

Arithmetic-Geometric Progression

$$\sum_{k=0}^{n-1} (a + kd)r^k = \frac{a - [a + (n-1)d]r^n}{1 - r} + \frac{dr(1 - r^{n-1})}{(1-r)^2} \qquad (r \neq 1)$$

$$\sum_{k=1}^{n} k^5 = \frac{1}{12} n^2(n+1)^2(2n^2 + 2n - 1)$$

$$\sum_{k=1}^{n} (2k-1) = n^2$$

$$\sum_{k=1}^{n} (2k-1)^2 = \frac{1}{3} n(4n^2 - 1)$$

$$\sum_{k=1}^{n} (2k-1)^3 = n^2(2n^2 - 1)$$

$$\gamma = \lim_{n\to\infty} \left(\sum_{m=1}^{n} \frac{1}{m} - \ln n \right) = 0.577215$$

ALGEBRAIC INEQUALITIES

Arithmetic-Geometric Inequality Let A_n and G_n denote respectively the arithmetic and the geometric means of a set of positive numbers $a_1, a_2, \ldots, a_n$. The $A_n \geq G_n$, i.e.,

$$\frac{a_1 + a_2 + \cdots + a_n}{n} \geq (a_1 a_2 \cdots a_n)^{1/n}$$

The equality holds only if all of the numbers a_i are equal.

Carleman's Inequality The arithmetic and geometric means just defined satisfy the inequality

$$\sum_{r=1}^{n} G_r \leq neA_n$$

or, equivalently,

$$\sum_{r=1}^{n} (a_1 a_2 \cdots a_r)^{1/r} \leq neA_n$$

where e is the best possible constant in this inequality.

Cauchy-Schwarz Inequality Let $a = (a_1, a_2, \ldots, a_n)$, $b = (b_1, b_2, \ldots, b_n)$, where the a_i's and b_i's are real or complex numbers. Then

$$\left| \sum_{k=1}^{n} a_k \bar{b}_k \right|^2 \leq \left(\sum_{k=1}^{n} |a_k|^2 \right) \left(\sum_{k=1}^{n} |b_k|^2 \right)$$

The equality holds if, and only if, the vectors a, b are linearly dependent (i.e., one vector is scalar times the other vector).

Minkowski's Inequality Let $a_1, a_2, \ldots, a_n$ and $b_1, b_2, \ldots, b_n$ be any two sets of complex numbers. Then for any real number $p > 1$,

$$\left(\sum_{k=1}^{n} |a_k + b_k|^p \right)^{1/p} \leq \left(\sum_{k=1}^{n} |a_k|^p \right)^{1/p} + \left(\sum_{k=1}^{n} |b_k|^p \right)^{1/p}$$

Hölder's Inequality Let $a_1, a_2, \ldots, a_n$ and $b_1, b_2, \ldots, b_n$ be any two sets of complex numbers, and let p and q be positive numbers with $1/p + 1/q = 1$. Then

$$\left| \sum_{k=1}^{n} a_k \bar{b}_k \right| \leq \left(\sum_{k=1}^{n} |a_k|^p \right)^{1/p} \left(\sum_{k=1}^{n} |b_k|^q \right)^{1/q}$$

The equality holds if, and only if, the sequences $|a_1|^p, |a_2|^p, \ldots, |a_n|^p$ and $|b_1|^q, |b_2|^q, \ldots, |b_n|^q$ are proportional and the argument (angle) of the complex numbers $a_k \bar{b}_k$ is independent of k. This last condition is of course automatically satisfied if $a_1, \ldots, a_n$ and $b_1, \ldots, b_n$ are positive numbers.

Lagrange's Inequality Let $a_1, a_2, \ldots, a_n$ and $b_1, b_2, \ldots, b_n$ be real numbers. Then

$$\left(\sum_{k=1}^{n} a_k b_k \right)^2 = \left(\sum_{k=1}^{n} a_k^2 \right) \left(\sum_{k=1}^{n} b_k^2 \right) - \sum_{1 \leq k \leq j \leq n} (a_k b_j - a_j b_k)^2$$

Example Two chemical engineers, John and Mary, purchase stock in the same company at times $t_1, t_2, \ldots, t_n$, when the price per share is respectively $p_1, p_2, \ldots, p_n$. Their methods of investment are different, however: John purchases x shares each time, whereas Mary invests P dollars each time (fractional shares can be purchased). Who is doing better?

While one can argue intuitively that the average cost per share for Mary does not exceed that for John, we illustrate a mathematical proof using inequalities. The average cost per share for John is equal to

$$\frac{\text{Total money invested}}{\text{Number of shares purchased}} = \frac{x \sum_{i=1}^{n} p_i}{nx} = \frac{1}{n} \sum_{i=1}^{n} p_i$$

The average cost per share for Mary is

$$\frac{nP}{\sum_{i=1}^{n} \frac{P}{p_i}} = \frac{n}{\sum_{i=1}^{n} \frac{1}{p_i}}$$

Thus the average cost per share for John is the arithmetic mean of $p_1, p_2, \ldots, p_n$, whereas that for Mary is the harmonic mean of these n numbers. Since the harmonic mean is less than or equal to the arithmetic mean for any set of positive numbers and the two means are equal only if $p_1 = p_2 = \cdots = p_n$, we conclude that the average cost per share for Mary is less than that for John if two of the prices p_i are distinct. One can also give a proof based on the Cauchy-Schwarz inequality. To this end, define the vectors

$$a = (p_1^{-1/2}, p_2^{-1/2}, \ldots, p_n^{-1/2}) \qquad b = (p_1^{1/2}, p_2^{1/2}, \ldots, p_n^{1/2})$$

Then $a \cdot b = 1 + \cdots + 1 = n$, and so by the Cauchy-Schwarz inequality

$$(a \cdot b)^2 = n^2 \leq \sum_{i=1}^{n} \frac{1}{p_i} \sum_{i=1}^{n} p_i$$

with the equality holding only if $p_1 = p_2 = \cdots = p_n$. Therefore

$$\frac{n}{\sum_{i=1}^{n} \frac{1}{p_i}} \leq \frac{\sum_{i=1}^{n} p_i}{n}$$

MENSURATION FORMULAS

Let A denote areas and V, volumes, in the following.

PLANE GEOMETRIC FIGURES WITH STRAIGHT BOUNDARIES

Triangles (see also "Plane Trigonometry") $A = ½bh$ where b = base, h = altitude.

Rectangle $A = ab$ where a and b are the lengths of the sides.

Parallelogram (opposite sides parallel) $A = ah = ab \sin \alpha$ where a, b are the lengths of the sides, h the height, and α the angle between the sides. See Fig. 3-3.

Rhombus (equilateral parallelogram) $A = ½ab$ where a, b are the lengths of the diagonals.

Trapezoid (four sides, two parallel) $A = ½(a + b)h$ where the lengths of the parallel sides are a and b, and h = height.

Quadrilateral (four-sided) $A = ½ab \sin \theta$ where a, b are the lengths of the diagonals and the acute angle between them is θ.

Regular Polygon of *n* Sides See Fig. 3-4.

$$A = \frac{1}{4} nl^2 \cot \frac{180°}{n} \quad \text{where } l = \text{length of each side}$$

$$R = \frac{l}{2} \csc \frac{180°}{n} \quad \text{where } R \text{ is the radius of the circumscribed circle}$$

$$r = \frac{l}{2} \cot \frac{180°}{n} \quad \text{where } r \text{ is the radius of the inscribed circle}$$

$$\beta = \frac{360°}{n}$$

$$\theta = \frac{(n-2)180°}{n}$$

$$l = 2r \tan \frac{\beta}{2} = 2R \sin \frac{\beta}{2}$$

Inscribed and Circumscribed Circles with Regular Polygon of* n *Sides Let l = length of one side.

Figure	n	Area	Radius of circumscribed circle	Radius of inscribed circle
Equilateral triangle	3	$0.4330\, l^2$	$0.5774\, l$	$0.2887\, l$
Square	4	$1.0000\, l^2$	$0.7071\, l$	$0.5000\, l$
Pentagon	5	$1.7205\, l^2$	$0.8507\, l$	$0.6882\, l$
Hexagon	6	$2.5981\, l^2$	$1.0000\, l$	$0.8660\, l$
Octagon	8	$4.8284\, l^2$	$1.3065\, l$	$1.2071\, l$
Decagon	10	$7.6942\, l^2$	$1.6180\, l$	$1.5388\, l$
Dodecagon	12	$11.1962\, l^2$	$1.8660\, l$	$1.9318\, l$

***Radius* r *of Circle Inscribed in Triangle with Sides* a, b, c**

$$r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}} \quad \text{where } s = ½(a + b + c)$$

Radius* R *of Circumscribed Circle

$$R = \frac{abc}{4\sqrt{s(s-a)(s-b)(s-c)}}$$

***Area of Regular Polygon of* n *Sides Inscribed in a Circle of Radius* r**

$$A = (nr^2/2) \sin (360°/n)$$

Perimeter of Inscribed Regular Polygon

$$P = 2nr \sin (180°/n)$$

***Area of Regular Polygon Circumscribed about a Circle of Radius* r**

$$A = nr^2 \tan (180°/n)$$

Perimeter of Circumscribed Regular Polygon

$$P = 2nr \tan \frac{180°}{n}$$

PLANE GEOMETRIC FIGURES WITH CURVED BOUNDARIES

Circle (Fig. 3-5) Let

C = circumference
r = radius
D = diameter
A = area
S = arc length subtended by θ
l = chord length subtended by θ
H = maximum rise of arc above chord, $r - H = d$
θ = central angle (rad) subtended by arc S

$C = 2\pi r = \pi D \qquad (\pi = 3.14159 \ldots)$

$S = r\theta = ½D\theta$

$l = 2\sqrt{r^2 - d^2} = 2r \sin (\theta/2) = 2d \tan (\theta/2)$

$$d = \frac{1}{2}\sqrt{4r^2 - l^2} = \frac{1}{2} l \cot \frac{\theta}{2}$$

$$\theta = \frac{S}{r} = 2 \cos^{-1} \frac{d}{r} = 2 \sin^{-1} \frac{l}{D}$$

$$A \text{ (circle)} = \pi r^2 = ¼\pi D^2$$

$$A \text{ (sector)} = ½rS = ½r^2\theta$$

$$A \text{ (segment)} = A \text{ (sector)} - A \text{ (triangle)} = ½r^2(\theta - \sin \theta)$$

$$= r^2 \cos^{-1} \frac{r-H}{r} - (r - H)\sqrt{2rH - H^2}$$

Ring (area between two circles of radii r_1 and r_2) The circles need not be concentric, but one of the circles must enclose the other.

$$A = \pi(r_1 + r_2)(r_1 - r_2) \qquad r_1 > r_2$$

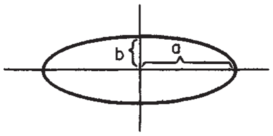

FIG. 3-6 Ellipse.

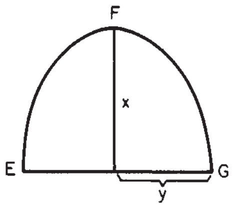

FIG. 3-7 Parabola.

Ellipse (Fig. 3-6) Let the semiaxes of the ellipse be a and b

$$A = \pi ab$$
$$C = 4aE(k)$$

where $e^2 = 1 - b^2/a^2$ and $E(e)$ is the complete elliptic integral of the second kind,

$$E(e) = \frac{\pi}{2}\left[1 - \left(\frac{1}{2}\right)^2 e^2 + \cdots\right]$$

[an approximation for the circumference $C = 2\pi\sqrt{(a^2 + b^2)/2}$].

Parabola (Fig. 3-7)

$$\text{Length of arc } EFG = \sqrt{4x^2 + y^2} + \frac{y^2}{2x}\ln\frac{2x + \sqrt{4x^2 + y^2}}{y}$$

$$\text{Area of section } EFG = \frac{4}{3}xy$$

Catenary (the curve formed by a cord of uniform weight suspended freely between two points A, B; Fig. 3-8)

$$y = a \cosh (x/a)$$

Length of arc between points A and B is equal to $2a \sinh (L/a)$. Sag of the cord is $D = a \cosh (L/a) - 1$.

SOLID GEOMETRIC FIGURES WITH PLANE BOUNDARIES

Cube Volume $= a^3$; total surface area $= 6a^2$; diagonal $= a\sqrt{3}$, where a = length of one side of the cube.

Rectangular Parallelepiped Volume $= abc$; surface area $= 2(ab + ac + bc)$; diagonal $= \sqrt{a^2 + b^2 + c^2}$, where a, b, c are the lengths of the sides.

Prism Volume = (area of base) × (altitude); lateral surface area = (perimeter of right section) × (lateral edge).

Pyramid Volume = ⅓ (area of base) × (altitude); lateral area of regular pyramid = ½ (perimeter of base) × (slant height) = ½ (number of sides) (length of one side) (slant height).

Frustum of Pyramid (formed from the pyramid by cutting off the top with a plane

$$V = \tfrac{1}{3}(A_1 + A_2 + \sqrt{A_1 \cdot A_2})h$$

where h = altitude and A_1, A_2 are the areas of the base; lateral area of a regular figure = ½ (sum of the perimeters of base) × (slant height).

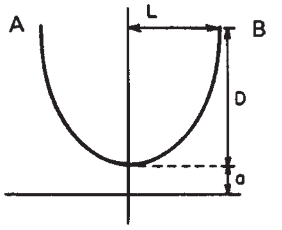

FIG. 3-8 Catenary.

Volume and Surface Area of Regular Polyhedra with Edge *l*

Type of surface	Name	Volume	Surface area
4 equilateral triangles	Tetrahedron	$0.1179\, l^3$	$1.7321\, l^2$
6 squares	Hexahedron (cube)	$1.0000\, l^3$	$6.0000\, l^2$
8 equilateral triangles	Octahedron	$0.4714\, l^3$	$3.4641\, l^2$
12 pentagons	Dodecahedron	$7.6631\, l^3$	$20.6458\, l^2$
20 equilateral triangles	Icosahedron	$2.1817\, l^3$	$8.6603\, l^2$

SOLIDS BOUNDED BY CURVED SURFACES

Cylinders (Fig. 3-9) V = (area of base) × (altitude); lateral surface area = (perimeter of right section) × (lateral edge).

Right Circular Cylinder $V = \pi\,(\text{radius})^2 \times (\text{altitude})$; lateral surface area = 2π (radius) × (altitude).

Truncated Right Circular Cylinder

$$V = \pi r^2 h;\ \text{lateral area} = 2\pi rh$$
$$h = \tfrac{1}{2}(h_1 + h_2)$$

Hollow Cylinders Volume $= \pi h(R^2 - r^2)$, where r and R are the internal and external radii and h is the height of the cylinder.

Sphere (Fig. 3-10)

$$V\,(\text{sphere}) = \tfrac{4}{3}\pi R^3,\ \tfrac{1}{6}\pi D^3$$
$$V\,(\text{spherical sector}) = \tfrac{2}{3}\pi R^2 h = \tfrac{1}{6}\pi h_1(3r_2^2 + h_1^2)$$
$$V\,(\text{spherical segment of one base}) = \tfrac{1}{6}\pi h_1(3r_2^2 + h_1^2)$$
$$V\,(\text{spherical segment of two bases}) = \tfrac{1}{6}\pi h_2(3r_1^2 + 3r_2^2 + h_2^2)$$
$$A\,(\text{sphere}) = 4\pi R^2 = \pi D^2$$
$$A\,(\text{zone}) = 2\pi Rh = \pi Dh$$

A (lune on the surface included between two great circles, the inclination of which is θ radians) $= 2R^2\theta$.

Cone V = ⅓ (area of base) × (altitude).

Right Circular Cone $V = (\pi/3)\, r^2 h$, where h is the altitude and r is the radius of the base; curved surface area $= \pi r\sqrt{r^2 + h^2}$, curved surface of the frustum of a right cone $= \pi(r_1 + r_2)\sqrt{h^2 + (r_1 - r_2)^2}$, where r_1, r_2 are the radii of the base and top, respectively, and h is the altitude; volume of the frustum of a right cone $= \pi(h/3)(r_1^2 + r_1 r_2 + r_2^2) = h/3(A_1 + A_2 + \sqrt{A_1 A_2})$, where A_1 = area of base and A_2 = area of top.

Ellipsoid $V = (4/3)\,\pi abc$, where a, b, c are the lengths of the semiaxes.

Torus (obtained by rotating a circle of radius r about a line whose distance is $R > r$ from the center of the circle)

$$V = 2\pi^2 Rr^2 \qquad \text{Surface area} = 4\pi^2 Rr$$

Prolate Spheroid (formed by rotating an ellipse about its major axis [$2a$])

$$\text{Surface area} = 2\pi b^2 + 2\pi(ab/e)\sin^{-1} e \qquad V = \tfrac{4}{3}\pi ab^2$$

where a, b are the major and minor axes and e = eccentricity ($e < 1$).

Oblate Spheroid (formed by the rotation of an ellipse about its minor axis [$2b$]) Data as given previously.

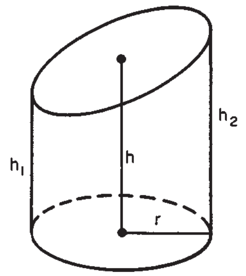

FIG. 3-9 Cylinder.

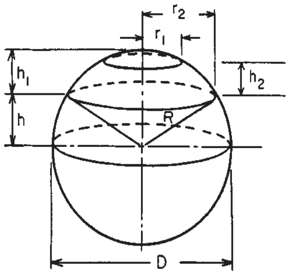

FIG. 3-10 Sphere.

$$\text{Surface area} = 2\pi a^2 + \pi \frac{b^2}{e} \ln \frac{1+e}{1-e} \qquad V = \tfrac{4}{3}\pi a^2 b$$

MISCELLANEOUS FORMULAS

See also "Differential and Integral Calculus."

Volume of a Solid Revolution (the solid generated by rotating a plane area about the x axis)

$$V = \pi \int_a^b [f(x)]^2 \, dx$$

where $y = f(x)$ is the equation of the plane curve and $a \le x \le b$.

Area of a Surface of Revolution

$$S = 2\pi \int_a^b y \, ds$$

where $ds = \sqrt{1 + (dy/dx)^2}\, dx$ and $y = f(x)$ is the equation of the plane curve rotated about the x axis to generate the surface.

Area Bounded by $f(x)$, the x Axis, and the Lines $x = a$, $x = b$

$$A = \int_a^b f(x) \, dx \qquad [f(x) \ge 0]$$

Length of Arc of a Plane Curve

If $y = f(x)$,

$$\text{Length of arc } s = \int_a^b \sqrt{1 + \left(\frac{dy}{dx}\right)^2} \, dx$$

If $x = g(y)$,

$$\text{Length of arc } s = \int_c^d \sqrt{1 + \left(\frac{dx}{dy}\right)^2} \, dy$$

If $x = f(t)$, $y = g(t)$,

$$\text{Length of arc } s = \int_{t_0}^{t_1} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} \, dt$$

In general, $(ds)^2 = (dx)^2 + (dy)^2$.

Theorems of Pappus (for volumes and areas of surfaces of revolution)

1. If a plane area is revolved about a line which lies in its plane but does not intersect the area, then the volume generated is equal to the product of the area and the distance traveled by the area's center of gravity.

2. If an arc of a plane curve is revolved about a line that lies in its plane but does not intersect the arc, then the surface area generated by the arc is equal to the product of the length of the arc and the distance traveled by its center of gravity.

These theorems are useful for determining volumes V and surface areas S of solids of revolution if the centers of gravity are known. If S and V are known, the centers of gravity may be determined.

IRREGULAR AREAS AND VOLUMES

Irregular Areas Let $y_0, y_1, \ldots, y_n$ be the lengths of a series of equally spaced parallel chords and h be their distance apart. The area of the figure is given approximately by any of the following:

$$A_T = (h/2)[(y_0 + y_n) + 2(y_1 + y_2 + \cdots + y_{n-1})] \qquad \text{(trapezoidal rule)}$$

$$A_s = (h/3)[(y_0 + y_n) + 4(y_1 + y_3 + y_5 + \cdots + y_{n-1}) + 2(y_2 + y_4 + \cdots + y_{n-2})] \qquad (n \text{ even, Simpson's rule})$$

The greater the value of n, the greater the accuracy of approximation.

Irregular Volumes To find the volume, replace the y's by cross-sectional areas A_j and use the results in the preceding equations.

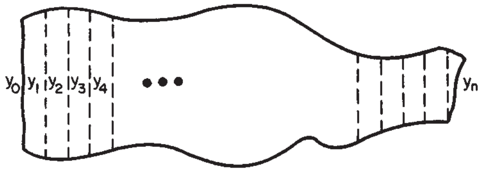

FIG. 3-11 Irregular area.

ELEMENTARY ALGEBRA

REFERENCES: 20, 102, 108, 191, 269, 277.

OPERATIONS ON ALGEBRAIC EXPRESSIONS

An algebraic expression will here be denoted as a combination of letters and numbers such as

$$3ax - 3xy + 7x^2 + 7x^{3/2} - 2.8xy$$

Addition and Subtraction Only like terms can be added or subtracted in two algebraic expressions.

Example $(3x + 4xy - x^2) + (3x^2 + 2x - 8xy) = 5x - 4xy + 2x^2$.

Example $(2^x + 3xy - 4x^{1/2}) + (3^x + 6x - 8xy) = 2^x + 3^x + 6x - 5xy - 4x^{1/2}$.

Multiplication Multiplication of algebraic expressions is term by term, and corresponding terms are combined.

Example $(2x + 3y - 2xy)(3 + 3y) = 6x + 9y + 9y^2 - 6xy^2$.

Division This operation is analogous to that in arithmetic.

Example Divide $3e^{2x} + e^x + 1$ by $e^x + 1$.

$$\begin{array}{rl} & \text{Dividend} \\ \text{Divisor } e^x + 1 \,|\, & 3e^{2x} + e^x + 1 \quad \underline{3e^x - 2} \text{ quotient} \\ & \underline{3e^{2x} + 3e^x} \\ & -2e^x + 1 \\ & \underline{-2e^x - 2} \\ & +3 \text{ (remainder)} \end{array}$$

Therefore, $3e^{2x} + e^x + 1 = (e^x + 1)(3e^x - 2) + 3$.

Operations with Zero All numerical computations (except division) can be done with zero: $a + 0 = 0 + a = a$; $a - 0 = a$; $0 - a = -a$; $(a)(0) = 0$; $a^0 = 1$ if $a \ne 0$; $0/a = 0$, $a \ne 0$. $a/0$ and $0/0$ have no meaning.

Fractional Operations

$$-\frac{x}{y} = -\left(\frac{-x}{-y}\right) = \frac{x}{-y} = \frac{-x}{y}; \quad \frac{x}{y} = \frac{-x}{-y}; \quad \frac{x}{y} = \frac{ax}{ay}, \text{ if } a \ne 0.$$

$$\frac{x}{y} \pm \frac{z}{y} = \frac{x \pm z}{y}; \quad \left(\frac{x}{y}\right)\left(\frac{z}{t}\right) = \frac{xz}{yt}; \quad \frac{x/y}{z/t} = \left(\frac{x}{y}\right)\left(\frac{t}{z}\right) = \frac{xt}{yz}$$

Factoring That process of analysis consisting of reducing a given expression into the product of two or more simpler expressions called *factors.* Some of the more common expressions are factored here:

(1) $(x^2 - y^2) = (x - y)(x + y)$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

(2) $x^2 + 2xy + y^2 = (x + y)^2$

(3) $x^2 + ax + b = (x + c)(x + d)$ where $c + d = a$, $cd = b$

(4) $by^2 + cy + d = (ey + f)(gy + h)$ where $eg = b$, $fg + eh = c$, $fh = d$

(5) $x^2 + y^2 + z^2 + 2yz + 2xz + 2xy = (x + y + z)^2$

(6) $x^2 - y^2 - z^2 - 2yz = (x - y - z)(x + y + z)$

(7) $x^2 + y^2 + z^2 - 2xy - 2xz + 2yz = (x - y - z)^2$

(8) $x^3 - y^3 = (x - y)(x^2 + xy + y^2)$

(9) $(x^3 + y^3) = (x + y)(x^2 - xy + y^2)$

(10) $(x^4 - y^4) = (x - y)(x + y)(x^2 + y^2)$

(11) $x^5 + y^5 = (x + y)(x^4 - x^3y + x^2y^2 - xy^3 + y^4)$

(12) $x^n - y^n = (x - y)(x^{n-1} + x^{n-2}y + x^{n-3}y^2 + \cdots + y^{n-1})$

Laws of Exponents

$(a^n)^m = a^{nm}$; $a^{n+m} = a^n \cdot a^m$; $a^{n/m} = (a^n)^{1/m}$; $a^{n-m} = a^n/a^m$; $a^{1/m} = \sqrt[m]{a}$; $a^{1/2} = \sqrt{a}$; $\sqrt{x^2} = |x|$ (absolute value of x). For $x > 0$, $y > 0$, $\sqrt{xy} = \sqrt{x}\sqrt{y}$; for $x > 0$ $\sqrt{x^m} = x^{m/n}$; $\sqrt[n]{1/x} = 1/\sqrt{x}$

THE BINOMIAL THEOREM

If n is a positive integer,

$$(a + b)^n = a^n + na^{n-1}b + \frac{n(n-1)}{2!}a^{n-2}b^2 + \frac{n(n-1)(n-2)}{3!}a^{n-3}b^3 + \cdots + b^n = \sum_{j=0}^{n}\binom{n}{j}a^{n-j}b^j$$

where $\binom{n}{j} = \frac{n!}{j!(n-j)!}$ = number of combinations of n things taken j at a time. $n! = 1 \cdot 2 \cdot 3 \cdot 4 \cdots n$, $0! = 1$.

Example Find the sixth term of $(x + 2y)^{12}$. The sixth term is obtained by setting $j = 5$. It is

$$\binom{12}{5}x^{12-5}(2y)^5 = 792x^7(2y)^5$$

Example $\sum_{j=0}^{14}\binom{n}{j} = (1 + 1)^{14} = 2^{14}$.

If n is not a positive integer, the sum formula no longer applies and an infinite series results for $(a + b)^n$. The coefficients are obtained from the first formulas in this case.

Example $(1 + x)^{1/2} = 1 + \frac{1}{2}x - \frac{1}{2} \cdot \frac{1}{4}x^2 + \frac{1}{2} \cdot \frac{1}{4} \cdot \frac{3}{6}x^3 \cdots$ (convergent for $x^2 < 1$).

Additional discussion is under "Infinite Series."

PROGRESSIONS

An arithmetic progression is a succession of terms such that each term, except the first, is derivable from the preceding by the addition of a quantity d called the common difference. All arithmetic progressions have the form a, $a + d$, $a + 2d$, $a + 3d$, ... With a = first term, l = last term, d = common difference, n = number of terms, and s = sum of the terms, the following relations hold:

$$l = a + (n - 1)d = -\frac{d}{2} + \sqrt{2ds + \left(a - \frac{d}{2}\right)^2}$$

$$= \frac{s}{n} + \frac{(n-1)}{2}d$$

$$s = \frac{n}{2}[2a + (n - 1)d] = \frac{n}{2}(a + l) = \frac{n}{2}[2l - (n - 1)d]$$

$$a = l - (n - 1)d = \frac{s}{n} - \frac{(n-1)d}{2} = \frac{2s}{n} - l$$

$$d = \frac{l - a}{n - 1} = \frac{2(s - an)}{n(n-1)} = \frac{2(nl - s)}{n(n-1)}$$

$$n = \frac{l - a}{d} + 1 = \frac{2s}{l + a} = \frac{2l + d + \sqrt{(2l + d)^2 - 8ds}}{2d}$$

The **arithmetic mean or average** of two numbers a, b is $(a + b)/2$; of n numbers $a_1, \ldots, a_n$ is $(a_1 + a_2 + \cdots + a_n)/n$.

A **geometric progression** is a succession of terms such that each term, except the first, is derivable from the preceding by the multiplication of a quantity r called the common ratio. All such progressions have the form a, ar, ar^2, . . . , ar^{n-1}. With a = first term, l = last term, r = ratio, n = number of terms, s = sum of the terms, the following relations hold:

$$l = ar^{n-1} = \frac{[a + (r - 1)s]}{r} = \frac{(r-1)sr^{n-1}}{r^n - 1}$$

$$s = \frac{a(r^n - 1)}{r - 1} = \frac{a(1 - r^n)}{1 - r} = \frac{rl - a}{r - 1} = \frac{lr^n - l}{r^n - r^{n-1}}$$

$$a = \frac{l}{r^{n-l}} = \frac{(r-1)s}{r^n - 1} \quad r = \frac{s - a}{s - l} \quad \log r = \frac{\log l - \log a}{n - 1}$$

$$n = \frac{\log l - \log a}{\log r} + 1 = \frac{\log[a + (r - 1)s] - \log a}{\log r}$$

The geometric mean of two nonnegative numbers a, b is $\sqrt{ab}$; of n numbers is $(a_1a_2 \ldots a_n)^{1/n}$.

Example Find the sum of $1 + \frac{1}{2} + \frac{1}{4} + \cdots + \frac{1}{64}$. Here $a = 1$, $r = \frac{1}{2}$, $n = 7$. Thus

$$s = \frac{\frac{1}{2}(\frac{1}{64}) - 1}{\frac{1}{2} - 1} = 127/64$$

$$s = a + ar + ar^2 + \cdots + ar^{n-1} = \frac{a}{1 - r} - \frac{ar^n}{1 - r}$$

If $|r| < 1$, then $\lim_{n\to\infty} s = \frac{a}{1 - r}$

which is called the sum of the infinite geometric progression.

Example The present worth (PW) of a series of cash flows C_k at the end of year k is

$$\mathrm{PW} = \sum_{k=1}^{n}\frac{C_k}{(1 + i)^k}$$

where i is an assumed interest rate. (Thus the present worth always requires specification of an interest rate.) If all the payments are the same, $C_k = R$, the present worth is

$$\mathrm{PW} = R\sum_{k=1}^{n}\frac{1}{(1 + i)^k}$$

This can be rewritten as

$$\mathrm{PW} = \frac{R}{1 + i}\sum_{k=1}^{n}\frac{1}{(1 + i)^{k-1}} = \frac{R}{1 + i}\sum_{j=0}^{n-1}\frac{1}{(1 + i)^j}$$

This is a geometric series with $r = 1/(1 + i)$ and $a = R/(1 + i)$. The formulas above give

$$\mathrm{PW}\ (=s) = \frac{R}{i}\,\frac{(1 + i)^n - 1}{(1 + i)^n}$$

The same formula applies to the value of an annuity (PW) now, to provide for equal payments R at the end of each of n years, with interest rate i.

A progression of the form a, $(a + d)r$, $(a + 2d)r^2$, $(a + 3d)r^3$, etc., is a combined arithmetic and geometric progression. The sum of n such terms is

$$s = \frac{a - [a + (n - 1)d]r^n}{I - r} + \frac{rd(1 - r^{n-1})}{(1 - r)^2}$$

If $|r| < 1$, $\lim_{n\to\infty} s = \frac{a}{1 - r} + rd/(1 - r)^2$.

The non-zero numbers a, b, c, etc., form a harmonic progression if their reciprocals $1/a$, $1/b$, $1/c$, etc., form an arithmetic progression.

Example The progression 1, ⅓, ⅕, ⅐, . . . , $\frac{1}{31}$ is harmonic since 1, 3, 5, 7, . . . , 31 form an arithmetic progression.

The **harmonic mean** of two numbers a, b is $2ab/(a+b)$.

PERMUTATIONS, COMBINATIONS, AND PROBABILITY

Each separate arrangement of all or a part of a set of things is called a **permutation.** The number of permutations of n things taken r at a time, written

$$P(n, r) = \frac{n!}{(n-r)!} = n(n-1)(n-2) \cdots (n-r+1)$$

Example The permutations of a, b, c two at a time are ab, ac, ba, ca, cb, and bc. The formula is $P(3,2) = 3!/1! = 6$. The permutations of a, b, c three at a time are abc, bac, cab, acb, bca, and cba.

Each separate selection of objects that is possible irrespective of the order in which they are arranged is called a combination. The number of combinations of n things taken r at a time, written $C(n, r) = n!/[r!(n-r)!]$.

Example The combinations of a, b, c taken 2 at a time are ab, ac, bc; taken 3 at a time is abc.

An important relation is $r!\ C(n, r) = P(n, r)$.

If an event can occur in p ways and fail to occur in q ways, all ways being equally likely, the *probability* of its occurrence is $p/(p+q)$, and that of its failure $q/(p+q)$.

Example Two dice may be thrown in 36 separate ways. What is the probability of throwing such that their sum is 7? Seven may arise in 6 ways: 1 and 6, 2 and 5, 3 and 4, 4 and 3, 5 and 2, 6 and 1. The probability of shooting 7 is ⅙.

THEORY OF EQUATIONS

Linear Equations A linear equation is one of the first degree (i.e., only the first powers of the variables are involved), and the process of obtaining definite values for the unknown is called solving the equation. Every linear equation in one variable is written $Ax + B = 0$ or $x = -B/A$. Linear equations in n variables have the form

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= b_2 \\ &\vdots \\ a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mn}x_n &= b_m \end{aligned}$$

The solution of the system may then be found by elimination or matrix methods if a solution exists (see "Matrix Algebra and Matrix Computations").

Quadratic Equations Every quadratic equation in one variable is expressible in the form $ax^2 + bx + c = 0$. $a \neq 0$. This equation has two solutions, say, x_1, x_2, given by

$$\left.\begin{matrix} x_1 \\ x_2 \end{matrix}\right\} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

If a, b, c are real, the discriminant $b^2 - 4ac$ gives the character of the roots. If $b^2 - 4ac > 0$, the roots are real and unequal. If $b^2 - 4ac < 0$, the roots are complex conjugates. If $b^2 - 4ac = 0$ the roots are **real** and **equal.**

Two quadratic equations in two variables can in general be solved only by numerical methods (see "Numerical Analysis and Approximate Methods"). If one equation is of the first degree, the other of the second degree, a solution may be obtained by solving the first for one unknown. This result is substituted in the second equation and the resulting quadratic equation solved.

Cubic Equations A cubic equation, in one variable, has the form $x^3 + bx^2 + cx + d = 0$. Every cubic equation having complex coefficients has three complex roots. If the coefficients are real numbers, then at least one of the roots must be real. The cubic equation $x^3 + bx^2 + cx + d = 0$ may be reduced by the substitution $x = y - (b/3)$ to the form $y^3 + py + q = 0$, where $p = \frac{1}{3}(3c - b^2)$, $q = \frac{1}{27}(27d - 9bc + 2b^3)$. This equation has the solutions $y_1 = A + B$, $y_2 = -\frac{1}{2}(A + B) + (i\sqrt{3}/2)(A - B)$, $y_3 = -\frac{1}{2}(A + B) - (i\sqrt{3}/2)(A - B)$, where $i^2 = -1$, $A = \sqrt[3]{-q/2 + \sqrt{R}}$, $B = \sqrt[3]{-q/2 - \sqrt{R}}$, and $R = (p/3)^3 + (q/2)^2$. If b, c, d are all real and if $R > 0$, there are one real root and two conjugate complex roots; if $R = 0$, there are three real roots, of which at least two are equal; if $R < 0$, there are three real unequal roots. If $R < 0$, these formulas are impractical. In this case, the roots are given by $y_k = \mp 2\sqrt{-p/3} \cos[(\phi/3) + 120k]$, $k = 0, 1, 2$ where

$$\phi = \cos^{-1}\sqrt{\frac{q^2/4}{-p^3/27}}$$

and the upper sign applies if $q > 0$, the lower if $q < 0$.

Example $x^3 + 3x^2 + 9x + 9 = 0$ reduces to $y^3 + 6y + 2 = 0$ under $x = y - 1$. Here $p = 6$, $q = 2$, $R = 9$. Hence $A = \sqrt[3]{2}$, $B = \sqrt[3]{-4}$. The desired roots in y are $\sqrt[3]{2} - \sqrt[3]{-4}$ and $-\frac{1}{2}(\sqrt[3]{2} - \sqrt[3]{4}) \pm (i\sqrt{3}/2)(\sqrt[3]{2} + \sqrt[3]{4})$. The roots in x are $x = y - 1$.

Example $y^3 - 7y + 7 = 0$. $p = -7$, $q = 7$, $R < 0$. Hence

$$x_k = -\sqrt{\frac{28}{3}} \cos\left(\frac{\phi}{3} + 120k\right)$$

where

$$\phi = \sqrt{\frac{27}{28}}, \quad \frac{\phi}{3} = 3°37'52''.$$

The roots are approximately −3.048916, 1.692020, and 1.356897.

Example Many equations of state involve solving cubic equations for the compressibility factor Z. For example, the Redlich-Kwong-Soave equation of state requires solving

$$Z^3 - Z^2 + cZ + d = 0, \quad d < 0$$

where c and d depend on critical constants of the chemical species. In this case, only positive solutions, $Z > 0$, are desired.

Quartic Equations See Ref. 118.

General Polynomials of the *n*th Degree Denote the general polynomial equation of degree n by

$$P(x) = a_0x^n + a_1x^{n-1} + \cdots + a_{n-1}x + a_n = 0$$

If $n > 4$, there is no formula which gives the roots of the general equation. For fourth and higher order (even third order), the roots can be found numerically (see "Numerical Analysis and Approximate Methods"). However, there are some general theorems that may prove useful.

Remainder Theorems When $P(x)$ is a polynomial and $P(x)$ is divided by $x - a$ until a remainder independent of x is obtained, this remainder is equal to $P(a)$.

Example $P(x) = 2x^4 - 3x^2 + 7x - 2$ when divided by $x + 1$ (here $a = -1$) results in $P(x) = (x + 1)(2x^3 - 2x^2 - x + 8) - 10$ where -10 is the remainder. It is easy to see that $P(-1) = -10$.

Factor Theorem If $P(a)$ is zero, the polynomial $P(x)$ has the factor $x - a$. In other words, if a is a root of $P(x) = 0$, then $x - a$ is a factor of $P(x)$.

If a number a is found to be a root of $P(x) = 0$, the division of $P(x)$ by $(x - a)$ leaves a polynomial of degree one less than that of the original equation, i.e., $P(x) = Q(x)(x - a)$. Roots of $Q(x) = 0$ are clearly roots of $P(x) = 0$.

Example $P(x) = x^3 - 6x^2 + 11x - 6 = 0$ has the root + 3. Then $P(x) = (x - 3)(x^2 - 3x + 2)$. The roots of $x^2 - 3x + 2 = 0$ are 1 and 2. The roots of $P(x)$ are therefore 1, 2, 3.

Fundamental Theorem of Algebra Every polynomial of degree n has exactly n real or complex roots, counting multiplicities.

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Every polynomial equation $a_0x^n + a_1x^{n-1} + \cdots + a_n = 0$ with *rational coefficients* may be rewritten as a polynomial, of the same degree, with *integral coefficients* by multiplying each coefficient by the least common multiple of the denominators of the coefficients.

Example The coefficients of $\frac{3}{2}x^4 + \frac{7}{3}x^3 - \frac{5}{6}x^2 + 2x - \frac{1}{6} = 0$ are rational numbers. The least common multiple of the denominators is $2 \times 3 = 6$. Therefore, the equation is equivalent to $9x^4 + 14x^3 - 5x^2 + 12x - 1 = 0$.

Upper Bound for the Real Roots Any number that exceeds all the roots is called an upper bound to the real roots. If the coefficients of a polynomial equation are all of like sign, there is no positive root. Such equations are excluded here since zero is the upper bound to the real roots. If the coefficient of the highest power of $P(x) = 0$ is negative, replace the equation by $-P(x) = 0$.

If in a polynomial $P(x) = c_0x^n + c_1x^{n-1} + \cdots + c_{n-1}x + c_n = 0$, with $c_0 > 0$, the first negative coefficient is preceded by k coefficients which are positive or zero, and if G denotes the greatest of the numerical values of the negative coefficients, then each real root is less than $1 + \sqrt[k]{G/c_0}$.

A lower bound to the negative roots of $P(x) = 0$ may be found by applying the rule to $P(-x) = 0$.

Example $P(x) = x^7 + 2x^5 + 4x^4 - 8x^2 - 32 = 0$. Here $k = 5$ (since 2 coefficients are zero), $G = 32$, $c_0 = 1$. The upper bound is $1 + \sqrt[5]{32} = 3$. $P(-x) = -x^7 - 2x^5 + 4x^4 - 8x^2 - 32 = 0$. $-P(-x) = x^7 + 2x^5 - 4x^4 + 8x^2 + 32 = 0$. Here $k = 3$, $G = 4$, $c_0 = 1$. The lower bound is $-(1 + \sqrt[3]{4}) \approx -2.587$. Thus all real roots r lie in the range $-2.587 < r < 3$.

Descartes Rule of Signs The number of positive real roots of a polynomial equation with real coefficients either is equal to the number v of its variations in sign or is less than v by a positive even integer. The number of negative roots of $P(x) = 0$ either is equal to the number of variations of sign of $P(-x)$ or is less than that number by a positive even integer.

Example $P(x) = x^4 + 3x^3 + x - 1 = 0$. $v = 1$; so $P(x)$ has one positive root. $P(-x) = x^4 - 3x^3 - x - 1$. Here $v = 1$; so $P(x)$ has one negative root. The other two roots are complex conjugates.

Example $P(x) = x^4 - x^2 + 10x - 4 = 0$. $v = 3$; so $P(x)$ has three or one positive roots. $P(-x) = x^4 - x^2 - 10x - 4$. $v = 1$; so $P(x)$ has exactly one negative root.

Numerical methods are often used to find the roots of polynomials. A detailed discussion of these techniques is given under "Numerical Analysis and Approximate Methods."

Determinants Consider the system of two linear equations

$$a_{11}x_1 + a_{12}x_2 = b_1$$
$$a_{21}x_1 + a_{22}x_2 = b_2$$

If the first equation is multiplied by a_{22} and the second by $-a_{12}$ and the results added, we obtain

$$(a_{11}a_{22} - a_{21}a_{12})x_1 = b_1a_{22} - b_2a_{12}$$

The expression $a_{11}a_{22} - a_{21}a_{12}$ may be represented by the symbol

$$\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11}a_{22} - a_{21}a_{12}$$

This symbol is called a determinant of second order. The value of the square array of n^2 quantities a_{ij}, where $i = 1, \ldots, n$ is the row index, $j = 1, \ldots, n$ the column index, written in the form

$$|A| = \begin{vmatrix} a_{11} & a_{12} & a_{13} \cdots a_{1n} \\ a_{21} & a_{22} & \cdots\cdots a_{2n} \\ \vdots & & \\ a_{n1} & a_{n2} & a_{n3} \cdots a_{nn} \end{vmatrix}$$

is called a determinant. The n^2 quantities a_{ij} are called the elements of the determinant. In the determinant $|A|$ let the ith row and jth column be deleted and a new determinant be formed having $n - 1$ rows and columns. This new determinant is called the minor of a_{ij} denoted M_{ij}.

Example $\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}$ The minor of a_{23} is $M_{23} = \begin{vmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{vmatrix}$

The cofactor A_{ij} of the element a_{ij} is the signed minor of a_{ij} determined by the rule $A_{ij} = (-1)^{i+j}M_{ij}$. The *value* of $|A|$ is obtained by forming any of the equivalent expressions $\sum_{j=1}^{n} a_{ij}A_{ij}$, $\sum_{i=1}^{n} a_{ij}A_{ij}$, where the elements a_{ij} must be taken from a single row or a single column of A.

Example

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix} = a_{31}A_{31} + a_{32}A_{32} + a_{33}A_{33}$$

$$= a_{31}\begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix} - a_{32}\begin{vmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{vmatrix} + a_{33}\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix}$$

In general, A_{ij} will be determinants of order $n - 1$, but they may in turn be expanded by the rule. Also,

$$\sum_{j=1}^{n} a_{ji}A_{jk} = \sum_{j=1}^{n} a_{ij}A_{jk} = \begin{cases} |A| & i = k \\ 0 & i \neq k \end{cases}$$

Fundamental Properties of Determinants

1. The value of a determinant $|A|$ is not changed if the rows and columns are interchanged.
2. If the elements of one row (or one column) of a determinant are all zero, the value of $|A|$ is zero.
3. If the elements of one row (or column) of a determinant are multiplied by the same constant factor, the value of the determinant is multiplied by this factor.
4. If one determinant is obtained from another by interchanging any two rows (or columns), the value of either is the negative of the value of the other.
5. If two rows (or columns) of a determinant are identical, the value of the determinant is zero.
6. If two determinants are identical except for one row (or column), the sum of their values is given by a single determinant obtained by adding corresponding elements of dissimilar rows (or columns) and leaving unchanged the remaining elements.

Example

$$\begin{vmatrix} 3 & 2 \\ 1 & 5 \end{vmatrix} + \begin{vmatrix} 4 & 2 \\ 7 & 5 \end{vmatrix} = 13 + 6 = 19 \quad \text{Directly}$$

$$\begin{vmatrix} 7 & 2 \\ 8 & 5 \end{vmatrix} = 35 - 16 = 19 \quad \text{By rule 6}$$

7. The value of a determinant is not changed if to the elements of any row (or column) are added a constant multiple of the corresponding elements of any other row (or column).
8. If all elements but one in a row (or column) are zero, the value of the determinant is the product of that element times its cofactor.

The evaluation of determinants using the definition is quite laborious. The labor can be reduced by applying the fundamental properties just outlined.

The solution of n linear equations (not all b_i zero)

$$a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n = b_1$$
$$a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n = b_2$$
$$\vdots \qquad\qquad \vdots$$
$$a_{n1}x_1 + a_{n2}x_2 + \cdots + a_{nn}x_n = b_n$$

where $|A| = \begin{vmatrix} a_{11} & \cdots & a_{1n} \\ a_{21} & \cdots & a_{2n} \\ \vdots & & \\ a_{n1} & \cdots & a_{nn} \end{vmatrix} \neq 0$

has a unique solution given by $x_1 = |B_1|/|A|$, $x_2 = |B_2|/|A|, \ldots, x_n = |B_n|/|A|$, where B_k is the determinant obtained from A by replacing its kth column by $b_1, b_2, \ldots, b_n$. This technique is called **Cramer's rule.** It requires more labor than the method of elimination and should not be used for computations.

ANALYTIC GEOMETRY

REFERENCES: 108, 188, 193, 260, 261, 268, 274, 282.

Analytic geometry uses algebraic equations and methods to study geometric problems. It also permits one to visualize algebraic equations in terms of geometric curves, which frequently clarifies abstract concepts.

PLANE ANALYTIC GEOMETRY

Coordinate Systems The basic concept of analytic geometry is the establishment of a one-to-one correspondence between the points of the plane and number pairs (x, y). This correspondence may be done in a number of ways. The rectangular or cartesian coordinate system consists of two straight lines intersecting at right angles (Fig. 3-12). A point is designated by (x, y), where x (the abscissa) is the distance of the point from the y axis measured parallel to the x axis, positive if to the right, negative to the left. y (ordinate) is the distance of the point from the x axis, measured parallel to the y axis, positive if above, negative if below the x axis. The **quadrants** are labeled 1, 2, 3, 4 in the drawing, the coordinates of points in the various quadrants having the depicted signs. Another common coordinate system is the polar coordinate system (Fig. 3-13). In this system the position of a point is designated by the pair (r, θ), $r = \sqrt{x^2 + y^2}$ being the distance to the origin 0(0,0) and θ being the angle the line r makes with the positive x axis (polar axis). To change from polar to rectangular coordinates, use $x = r \cos \theta$ and $y = r \sin \theta$. To change from rectangular to polar coordinates, use $r = \sqrt{x^2 + y^2}$ and $\theta = \tan^{-1}(y/x)$ if $x \neq 0$; $\theta = \pi/2$ if $x = 0$. The distance between two points (x_1, y_1), (x_2, y_2) is defined by $d = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$ in rectangular coordinates or by $d = \sqrt{r_1^2 + r_2^2 - 2r_1r_2 \cos(\theta_1 - \theta_2)}$ in polar coordinates. Other coordinate systems are sometimes used. For example, on the surface of a sphere latitude and longitude prove useful.

The Straight Line (Fig. 3-14) The slope m of a straight line is the tangent of the inclination angle θ made with the positive x axis. If (x_1, y_1) and (x_2, y_2) are any two points on the line, slope $= m = (y_2 - y_1)/(x_2 - x_1)$. The slope of a line parallel to the x axis is zero; parallel to the y axis, it is undefined. Two lines are parallel if and only if they have the same slope. Two lines are perpendicular if and only if the product of their slopes is -1 (the exception being that case when the lines are parallel to the coordinate axes). Every equation of the type $Ax + By + C = 0$ represents a straight line, and every straight line has an equation of this form. A straight line is determined by a variety of conditions:

Given conditions	Equation of line
(1) Parallel to x axis	$y = \text{constant}$
(2) Parallel y axis	$x = \text{constant}$
(3) Point (x_1, y_1) and slope m	$y - y_1 = m(x - x_1)$
(4) Intercept on y axis $(0, b)$, m	$y = mx + b$
(5) Intercept on x axis $(a, 0)$, m	$y = m(x - a)$
(6) Two points (x_1, y_1), (x_2, y_2)	$y - y_1 = \dfrac{y_2 - y_1}{x_2 - x_1}(x - x_1)$
(7) Two intercepts $(a, 0)$, $(0, b)$	$x/a + y/b = 1$

The angle β a line with slope m_1 makes with a line having slope m_2 is given by $\tan \beta = (m_2 - m_1)/(m_1m_2 + 1)$. A line is determined if the length and direction of the perpendicular to it (the normal) from the origin are given (see Fig. 3-15). Let p = length of the perpendicular and α the angle that the perpendicular makes with the positive x axis. The equation of the line is $x \cos \alpha + y \sin \alpha = p$. The equation of a line perpendicular to a given line of slope m and passing through a point (x_1, y_1) is $y - y_1 = -(1/m)(x - x_1)$. The distance from a point (x_1, y_1) to a line with equation $Ax + by + C = 0$ is

$$d = \frac{|Ax_1 + By_1 + C|}{\sqrt{A^2 + B^2}}$$

Example If it is known that centigrade C and Fahrenheit F are linearly related and when C = 0°, F = 32°; C = 100°, F = 212°, find the equation relating C and F and that point where C = F. By using the two-point form, the equation is

$$F - 32 = \frac{212 - 32}{100 - 0}(C - 0)$$

or $F = \frac{9}{5}C + 32$. Equivalently

$$C - 0 = \frac{100 - 0}{212 - 32}(F - 32)$$

or $C = \frac{5}{9}(F - 32)$. Letting C = F, we have from either equation F = C = −40.

Occasionally some nonlinear algebraic equations can be reduced to linear equations under suitable substitutions or changes of variables. In other words, certain curves become the graphs of lines if the scales or coordinate axes are appropriately transformed.

Example Consider $y = bx^n$. $B = \log b$. Taking logarithms $\log y = n \log x + \log b$. Let $Y = \log y$, $X = \log x$, $B = \log b$. The equation then has the form $Y = nX + B$, which is a linear equation. Consider $k = k_0 \exp(-E/RT)$, taking logarithms $\log_e k = \log_e k_0 - E/(RT)$. Let $Y = \log_e k$, $B = \log_e k_0$, and $m = -E/R$, $X = 1/T$, and the result is $Y = mX + B$. Next consider $y = a + bx^n$. If the substitution $t = x^n$ is made, then the graph of y is a straight line versus t.

Asymptotes The limiting position of the tangent to a curve as the point of contact tends to an infinite distance from the origin is called an **asymptote.** If the equation of a given curve can be expanded in a Laurent power series such that

$$f(x) = \sum_{k=0}^{n} a_k x^k + \sum_{k=0}^{n} \frac{b_k}{x^k}$$

and

$$\lim_{x\to\infty} f(x) = \sum_{k=0}^{n} a_k x^k$$

then the equation of the asymptote is $y = \sum_{k=0}^{n} a_k x^k$. If $n = 1$, then the asymptote is (in general oblique) a line. In this case, the equation of the asymptote may be written as

$$y = mx + b \qquad m = \lim_{x\to\infty} f'(x)$$

$$b = \lim_{x\to\infty} [f(x) - xf'(x)]$$

Geometric Properties of a Curve When the Equation Is Given The analysis of the properties of an equation is facilitated by the investigation of the equation by using the following techniques:

1. *Points of maximum, minimum, and inflection.* These may be investigated by means of the calculus.

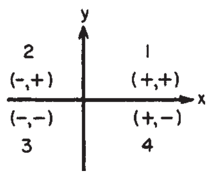

FIG. 3-12 Rectangular coordinates.

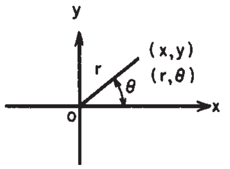

FIG. 3-13 Polar coordinates.

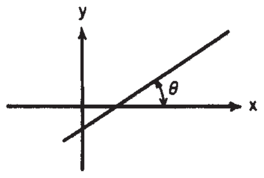

FIG. 3-14 Straight line.

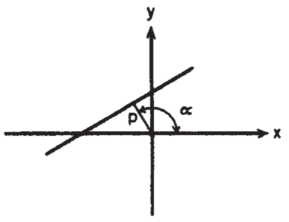

FIG. 3-15 Determination of line.

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

2. *Symmetry.* Let $F(x, y) = 0$ be the equation of the curve.

Condition on $F(x, y)$	Symmetry
$F(x, y) = F(-x, y)$	With respect to y axis
$F(x, y) = F(x, -y)$	With respect to x axis
$F(x, y) = F(-x, -y)$	With respect to origin
$F(x, y) = F(y, x)$	With respect to the line $y = x$

3. *Extent.* Only real values of x and y are considered in obtaining the points (x, y) whose coordinates satisfy the equation. The extent of them may be limited by the condition that negative numbers do not have real square roots.
4. *Intercepts.* Find those points where the curves of the function cross the coordinate axes.
5. *Asymptotes.* See preceding discussion.
6. *Direction at a point.* This may be found from the derivative of the function at a point. This concept is useful for distinguishing among a family of similar curves.

Example $y^2 = (x^2 + 1)/(x^2 - 1)$ is symmetric with respect to the x and y axis, the origin, and the line $y = x$. It has the vertical asymptotes $x = \pm 1$. When $x = 0$, $y^2 = -1$; so there are no y intercepts. If $y = 0$, $(x^2 + 1)/(x^2 - 1) = 0$; so there are no x intercepts. If $|x| < 1$, y^2 is negative; so $|x| > 1$. From $x^2 = (y^2 + 1)/(y^2 - 1)$, $y = \pm 1$ are horizontal asymptotes and $|y| > 1$. As $x \to 1^+$, $y \to +\infty$; as $x \to +\infty$, $y \to +1$. The graph is given in Fig. 3-16.

Conic Sections The curves included in this group are obtained from plane sections of the cone. They include the circle, ellipse, parabola, hyperbola, and degeneratively the point and straight line. A **conic** is the locus of a point whose distance from a fixed point called the **focus** is in a constant ratio to its distance from a fixed line, called the directrix. This ratio is the eccentricity e. If $e = 0$, the conic is a circle; if $0 < e < 1$, the conic is an ellipse; if $e = 1$, the conic is a parabola; if $e > 1$, the conic is a hyperbola. Every conic section is representable by an equation of second degree. Conversely, every equation of second degree in two variables represents a conic. The general equation of the second degree is $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$. Let Δ be defined as the determinant

$$\Delta = \begin{vmatrix} 2A & B & D \\ B & 2C & E \\ D & E & 2F \end{vmatrix}$$

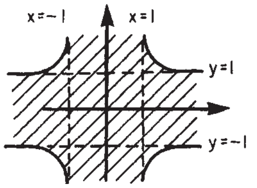

FIG. 3-16 Graph of $y^2 = (x^2 + 1)/(x^2 - 1)$

The table characterizes the curve represented by the equation.

	$B^2 - 4AC < 0$	$B^2 - 4AC = 0$	$B^2 - 4AC > 0$
$\Delta \neq 0$	$A\Delta < 0$ $A \neq C$, an ellipse $A\Delta < 0$ $A = C$, a circle $A\Delta > 0$, no locus	Parabola	Hyperbola
$\Delta = 0$	Point	2 parallel lines if $Q = D^2 + E^2 - 4(A + C)F > 0$ 1 straight line if $Q = 0$, no locus if $Q < 0$	2 intersecting straight lines

Example $3x^2 + 4xy - 2y^2 + 3x - 2y + 7 = 0$.

$$\Delta = \begin{vmatrix} 6 & 4 & 3 \\ 4 & -4 & -2 \\ 3 & -2 & 14 \end{vmatrix} = -596 \neq 0,\ B^2 - 4AC = 40 > 0$$

The curve is therefore a hyperbola.

To translate the axes to a new origin at (h, k), substitute for x and y in the original equation $x + h$ and $y + k$. Translation of the axes can always be accomplished to eliminate the linear terms in the second-degree equation in two variables having no xy term.

Example $x^2 + y^2 + 2x - 4y + 2 = 0$. Rewrite this as $x^2 + 2x + 1 + y^2 - 4y + 4 - 5 + 2 = 0$ or $(x + 1)^2 + (y - 2)^2 = 3$. Let $u = x + 1$, $v = y - 2$. Then $u^2 + v^2 = 3$. The axis has been translated to the new origin $(-1, 2)$.

The type of curve determined by a specific equation of the second degree can also be easily determined by reducing it to a standard form by translation and/or rotation. In the case in which the equation has no xy term, the procedure is merely to complete the squares of the terms in x and y separately.

To rotate the axes through an angle α, substitute for x the quantity $x \cos \alpha - y \sin \alpha$ and for y the quantity $x \sin \alpha + y \cos \alpha$. A rotation of the axes through $\alpha = \frac{1}{2} \cot^{-1} (A - C)/B$ will eliminate the cross-product term in the general second-degree equation.

Example Consider $3x^2 + 2xy + y^2 - 2x + 3y = 7$. A rotation of axes through $\alpha = \frac{1}{2} \cot^{-1} 1 = 22\frac{1}{2}°$ eliminates the cross-product term.

The following tabulation gives the form of the more common equations.

Polar equation	Type of curve
(1) $r = a$	Circle
(2) $r = 2a \cos \theta$	Circle
(3) $r = 2a \sin \theta$	Circle
(4) $r^2 - 2br \cos (\theta - \beta) + b^2 - a^2 = 0$	Circle at (b, β), radius a
(5) $r = \dfrac{ke}{1 - e \cos \theta}$	$e = 1$ parabola $0 < e < 1$ ellipse $e > 1$ hyperbola

Some common equations in parametric form are given below.

(1) $(x - h)^2 + (y - k)^2 = a^2$	$x = h + a \cos \theta$ $y = k + a \sin \theta$	Circle (Fig. 3-23) Parameter is angle θ.
(2) $\dfrac{(x - h)^2}{a^2} + \dfrac{(y - k)^2}{b^2} = 1$	$x = h + a \cos \phi$ $y = k + a \sin \phi$	Ellipse (Fig. 3-20) Parameter is angle ϕ.
(3) $z^2 + y^2 = a^2$	$x = \dfrac{-at}{\sqrt{t^2 + 1}}$ $y = \dfrac{a}{\sqrt{t^2 + 1}}$	Circle Parameter is $t = \dfrac{dy}{dx}$ = slope of tangent at (x, y).
(4) $y = a \cosh \dfrac{x}{a}$	$x = a \sinh^{-1} \dfrac{s}{a}$ $y^2 = a^2 + s^2$	Catenary (Fig. 3-24; such as hanging cable under gravity) Parameter s = arc length from $(0, a)$ to (x, y). See Fig. 3-24.
(5) Cycloid	$x = a(\phi - \sin \phi)$ $y = a(1 - \cos \phi)$

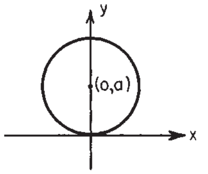

FIG. 3-19 Circle center $(0,a)$ $r = 2a \sin \theta$.

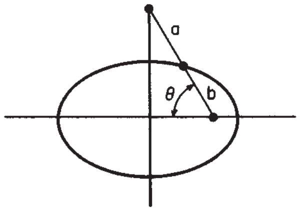

FIG. 3-20 Ellipse, $0 < e < 1$.

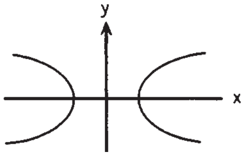

FIG. 3-21 Hyperbola, $e > 1$, $r = ke/(1 - e \cos \theta)$.

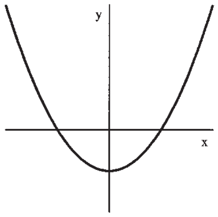

FIG. 3-22 Parabola, $e = 1$.

Circle at (b, β), radius a: $r^2 - 2br \cos (\theta - \beta) + b^2 - a^2 = 0$.

Graphs of Polar Equations The equation $r = 0$ corresponds to $x = 0$, $y = 0$ regardless of θ. The same point may be represented in several different ways; thus the point $(2, \pi/3)$ or $(2, 60°)$ has the following representations: $(2, 60°)$, $(2, -300°)$. These are summarized in $(2, 60° + n\ 360°)$, $n = 0, \pm 1, \pm 2$, or in radian measure $[2, (\pi/3) + 2n\pi]$, $n = 0, \pm 1, \pm 2$. Plotting of polar equations can be facilitated by the following steps:

1. Find those points where r is a maximum or minimum.
2. Find those values of θ where $r = 0$, if any.
3. Symmetry: The curve is symmetric about the origin if the equation is unchanged when θ is replaced by $\theta \pm \pi$, symmetric about the x axis if the equation is unchanged when θ is replaced by $-\theta$, and symmetric about the y axis if the equation is unchanged when θ is replaced by $\pi - \theta$.

Parametric Equations It is frequently useful to write the equations of a curve in terms of an auxiliary variable called a parameter. For example, a circle of radius a, center at (0, 0), can be written in the equivalent form $x = a \cos \theta$, $y = a \sin \phi$ where θ is the parameter. Similarly, $x = a \cos \phi$, $y = b \sin \phi$ are the parametric equations of the ellipse $x^2/a^2 + y^2/b^2 = 1$ with parameter ϕ.

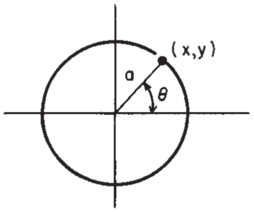

FIG. 3-23 Circle.

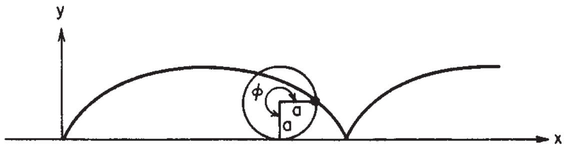

FIG. 3-24 Cycloid.

SOLID ANALYTIC GEOMETRY

Coordinate Systems The commonly used coordinate systems are three in number. Others may be used in specific problems (see Ref. 212). The **rectangular** (cartesian) system (Fig. 3-25) consists of mutually orthogonal axes x, y, z. A triple of numbers (x, y, z) is used to represent each point. The **cylindrical** coordinate system (r, θ, z; Fig. 3-26) is frequently used to locate a point in space. These are essentially the polar coordinates (r, θ) coupled with the z coordinate. As

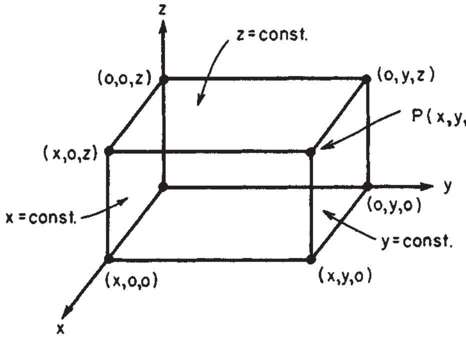

FIG. 3-25 Cartesian coordinates.

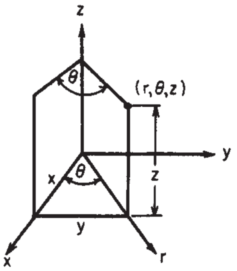

FIG. 3-26 Cylindrical coordinates.

before, $x = r\cos\theta$, $y = r\sin\theta$, $z = z$ and $r^2 = x^2 + y^2$, $y/x = \tan\theta$. If r is held constant and θ and z are allowed to vary, the locus of (r, θ, z) is a right circular cylinder of radius r along the z axis. The locus of $r = C$ is a circle, and θ = constant is a plane containing the z axis and making an angle θ with the xz plane. Cylindrical coordinates are convenient to use when the problem has an axis of symmetry.

The **spherical** coordinate system is convenient if there is a point of symmetry in the system. This point is taken as the origin and the coordinates (ρ, ϕ, θ) illustrated in Fig. 3-27. The relations are $x = \rho\sin\phi\cos\theta$, $y = \rho\sin\phi\sin\theta$, $z = \rho\cos\phi$, and $r = \rho\sin\phi$. θ = constant is a plane containing the z axis and making an angle θ with the xz plane. ϕ = constant is a cone with vertex at 0. ρ = constant is the surface of a sphere of radius ρ, center at the origin 0. Every point in the space may be given spherical coordinates restricted to the ranges $0 \le \phi \le \pi$, $\rho \ge 0$, $0 \le \theta < 2\pi$.

Lines and Planes The distance between two points (x_1, y_1, z_1), (x_2, y_2, z_2) is $d = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2}$. There is nothing in the geometry of three dimensions quite analogous to the slope of a line in the plane case. Instead of specifying the direction of a line by a trigonometric function evaluated for one angle, a trigonometric function evaluated for three angles is used. The angles α, β, γ that a line segment makes with the positive x, y, and z axes, respectively, are called the **direction angles** of the line, and $\cos\alpha$, $\cos\beta$, $\cos\gamma$ are called the **direction cosines.** Let (x_1, y_1, z_1), (x_2, y_2, z_2) be on the line. Then $\cos\alpha = (x_2 - x_1)/d$, $\cos\beta = (y_2 - y_1)/d$, $\cos\gamma = (z_2 - z_1)/d$, where d = the distance between the two points. Clearly $\cos^2\alpha + \cos^2\beta + \cos^2\gamma = 1$. If two lines are specified by the direction cosines $(\cos\alpha_1, \cos\beta_1, \cos\gamma_1)$, $(\cos\alpha_2, \cos\beta_2, \cos\gamma_2)$, then the angle θ between the lines is $\cos\theta = \cos\alpha_1\cos\alpha_2 + \cos\beta_1\cos\beta_2 + \cos\gamma_1\cos\gamma_2$. Thus the lines are perpendicular if and only if $\theta = 90°$ or $\cos\alpha_1\cos\alpha_2 + \cos\beta_1\cos\beta_2 + \cos\gamma_1\cos\gamma_2 = 0$. The equation of a line with direction cosines $(\cos\alpha, \cos\beta, \cos\gamma)$ passing through (x_1, y_1, z_1) is $(x - x_1)/\cos\alpha = (y - y_1)/\cos\beta = (z - z_1)/\cos\gamma$.

The equation of every plane is of the form $Ax + By + Cz + D = 0$. The numbers

$$\frac{A}{\sqrt{A^2 + B^2 + C^2}}, \frac{B}{\sqrt{A^2 + B^2 + C^2}}, \frac{C}{\sqrt{A^2 + B^2 + C^2}}$$

are direction cosines of the normal lines to the plane. The plane through the point (x_1, y_1, z_1) whose normals have these as direction cosines is $A(x - x_1) + B(y - y_1) + C(z - z_1) = 0$.

Example Find the equation of the plane through (1, 5, –2) perpendicular to the line $(x + 9)/7 = (y - 3)/-1 = z/8$. The numbers (7, –1, 8) are called **direction numbers.** They are a constant multiple of the direction cosines. $\cos\alpha = 7/114$, $\cos\beta = -1/114$, $\cos\gamma = 8/114$. The plane has the equation $7(x - 1) - 1(y - 5) + 8(z + 2) = 0$ or $7x - y + 8z + 14 = 0$.

The distance from the point (x_1, y_1, z_1) to the plane $Ax + By + Cz + D = 0$ is

$$d = \frac{|Ax_1 + By_1 + Cz_1 + D|}{\sqrt{A^2 + B^2 + C^2}}$$

Space Curves Space curves are usually specified as the set of points whose coordinates are given parametrically by a system of equations $x = f(t)$, $y = g(t)$, $z = h(t)$ in the parameter t.

Example The equation of a straight line in space is $(x - x_1)/a = (y - y_1)/b = (z - z_1)/c$. Since all these quantities must be equal (say, to t), we may write $x = x_1 + at$, $y = y_1 + bt$, $z = z_1 + ct$, which represent the parametric equations of the line.

Example The equations $z = a\cos\beta t$, $y = a\sin\beta t$, $z = bt$, a, β, b positive constants, represent a circular helix.

Surfaces The locus of points (x, y, z) satisfying $f(x, y, z) = 0$, broadly speaking, may be interpreted as a surface. The simplest surface is the **plane.** The next simplest is a **cylinder,** which is a surface generated by a straight line moving parallel to a given line and passing through a given curve.

Example The parabolic cylinder $y = x^2$ (Fig. 3-28) is generated by a straight line parallel to the z axis passing through $y = x^2$ in the plane $z = 0$.

PLANE TRIGONOMETRY

REFERENCES: 20, 108, 131, 158, 166, 202.

ANGLES

An angle is generated by the rotation of a line about a fixed center from some initial position to some terminal position. If the rotation is clockwise, the angle is negative; if it is counterclockwise, the angle is positive. Angle size is unlimited. If α, β are two angles such that $\alpha + \beta = 90°$, they are complementary; they are supplementary if $\alpha + \beta = 180°$. Angles are most commonly measured in the sexagesimal system or by radian measure. In the first system there are 360 degrees in one complete revolution; one degree = 1/90 of a right angle. The degree is subdivided into 60 minutes; the minute is subdivided into 60 seconds. In the radian system one radian is the angle at the center of a circle subtended by an arc whose length is equal to the radius of the circle. Thus 2π rad = 360°; 1 rad = 57.29578°; 1° = 0.01745 rad; 1 min = 0.00029089 rad. The advantage of radian measure is that it is *dimensionless.* The quadrants are conventionally labeled as Fig. 3-38 shows.

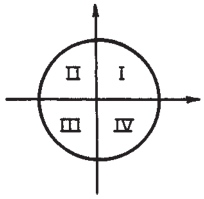

FIG. 3-38 Quadrants.

FUNCTIONS OF CIRCULAR TRIGONOMETRY

The trigonometric functions of angles are the ratios between the various sides of the reference triangles shown in Fig. 3-39 for the various quadrants. Clearly $r = \sqrt{x^2 + y^2} \geq 0$. The fundamental functions (see Figs. 3-40, 3-41, 3-42) are

Values of the Trigonometric Functions for Common Angles

θ°	θ, rad	sin θ	cos θ	tan θ
0	0	0	1	0
30	π/6	1/2	$\sqrt{3}/2$	$\sqrt{3}/3$
45	π/4	$\sqrt{2}/2$	$\sqrt{2}/2$	1
60	π/3	$\sqrt{3}/2$	1/2	$\sqrt{3}$
90	π/2	1	0	+∞

If $90° \le \theta \le 180°$, $\sin\theta = \sin(180° - \theta)$; $\cos\theta = -\cos(180° - \theta)$; $\tan\theta = -\tan(180° - \theta)$. If $180° \le \theta \le 270°$, $\sin\theta = -\sin(270° - \theta)$; $\cos\theta = -\cos(270° - \theta)$; $\tan\theta = \tan(270° - \theta)$. If $270° \le \theta \le 360°$, $\sin\theta = -\sin(360° - \theta)$; $\cos\theta = \cos(360° - \theta)$; $\tan\theta = -\tan(360° - \theta)$. The reciprocal properties may be used to find the values of the other functions.

If it is desired to find the angle when a function of it is given, the procedure is as follows: There will in general be two angles between 0° and 360° corresponding to the given value of the function.

Given ($a > 0$)	Find an acute angle θ_0 such that	Required angles are
$\sin\theta = +a$	$\sin\theta_0 = a$	θ_0 and $(180° - \theta_0)$
$\cos\theta = +a$	$\cos\theta_0 = a$	θ_0 and $(360° - \theta_0)$
$\tan\theta = +a$	$\tan\theta_0 = a$	θ_0 and $(180° + \theta_0)$
$\sin\theta = -a$	$\sin\theta_0 = a$	$180° + \theta_0$ and $360° - \theta_0$
$\cos\theta = -a$	$\cos\theta_0 = a$	$180° - \theta_0$ and $180° + \theta_0$
$\tan\theta = -a$	$\tan\theta_0 = a$	$180° - \theta_0$ and $360° - \theta_0$

Relations between Functions of a Single Angle $\sec\theta = 1/\cos\theta$; $\csc\theta = 1/\sin\theta$, $\tan\theta = \sin\theta/\cos\theta = \sec\theta/\csc\theta = 1/\cot\theta$; $\sin^2\theta + \cos^2\theta = 1$; $1 + \tan^2\theta = \sec^2\theta$; $1 + \cot^2\theta = \csc^2\theta$. For $0 \le \theta \le 90°$ the following results hold:

$$\sin\theta = \cos\theta/\cot\theta = \sqrt{1 - \cos^2\theta} = \cos\theta\tan\theta$$

$$= \frac{\tan\theta}{\sqrt{1 + \tan^2\theta}} = \frac{1}{\sqrt{1 + \cot^2\theta}} = 2\sin\left(\frac{\theta}{2}\right)\cos\left(\frac{\theta}{2}\right)$$

and $$\cos\theta = \sqrt{1 - \sin^2\theta} = \frac{1}{\sqrt{1 + \tan^2\theta}}$$

$$= \frac{\cot\theta}{\sqrt{1 + \cot^2\theta}} = \frac{\sin\theta}{\tan\theta} = \cos^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta}{2}\right)$$

The cofunction property is very important. $\cos\theta = \sin(90° - \theta)$, $\sin\theta = \cos(90° - \theta)$, $\tan\theta = \cot(90° - \theta)$, $\cot\theta = \tan(90° - \theta)$, etc.

Functions of Negative Angles $\sin(-\theta) = -\sin\theta$, $\cos(-\theta) = \cos\theta$, $\tan(-\theta) = -\tan\theta$, $\sec(-\theta) = \sec\theta$, $\csc(-\theta) = -\csc\theta$, $\cot(-\theta) = -\cot\theta$.

Identities

Sum and Difference Formulas Let x, y be two angles. $\sin(x \pm y) = \sin x\cos y \pm \cos x\sin y$; $\cos(x \pm y) = \cos x\cos y \mp \sin x\sin y$; $\tan(x \pm y) = (\tan x \pm \tan y)/(1 \mp \tan x\tan y)$; $\sin x \pm \sin y = 2\sin\frac{1}{2}(x \pm y)\cos\frac{1}{2}(x \mp y)$; $\cos x + \cos y = 2\cos\frac{1}{2}(x + y)\cos\frac{1}{2}(x - y)$; $\cos x - \cos y = -2\sin\frac{1}{2}(x + y)\sin\frac{1}{2}(x - y)$; $\tan x \pm \tan y = [\sin(x \pm y)]/(\cos x\cos y)$; $\sin^2 x - \sin^2 y = \cos^2 y - \cos^2 x = \sin(x + y)\sin(x - y)$; $\cos^2 x - \sin^2 y = \cos^2 y - \sin^2 x = \cos(x + y)\cos(x - y)$; $\sin(45° + x) = \cos(45° - x)$; $\sin(45° - x) = \cos(45° + x)$; $\tan(45° \pm x) = \cot(45° \mp x)$. $A\cos x + B\sin x = \sqrt{A^2 + B^2}\sin(\alpha + x) = \sqrt{A^2 + B^2}\cos(\beta - x)$ where $\tan\alpha = A/B$, $\tan\beta = B/A$; both α and β are positive acute angles.

Multiple and Half Angle Identities Let x = angle, $\sin 2x = 2\sin x\cos x$; $\sin x = 2\sin\frac{1}{2}x\cos\frac{1}{2}x$; $\cos 2x = \cos^2 x - \sin^2 x = 1 - 2\sin^2 x = 2\cos^2 x - 1$. $\tan 2x = (2\tan x)/(1 - \tan^2 x)$; $\sin 3x = 3\sin x - 4\sin^3 x$; $\cos 3x = 4\cos^3 x - 3\cos x$. $\tan 3x = (3\tan x - \tan^3 x)/(1 - 3\tan^2 x)$; $\sin 4x = 4\sin x\cos x - 8\sin^3 x\cos x$; $\cos 4x = 8\cos^4 x - 8\cos^2 x + 1$.

$$\sin\left(\frac{x}{2}\right) = \sqrt{\tfrac{1}{2}(1 - \cos x)}$$

$$\cos\left(\frac{x}{2}\right) = \sqrt{\tfrac{1}{2}(1 + \cos x)}$$

$$\tan\left(\frac{x}{2}\right) = \sqrt{\frac{1 - \cos x}{1 + \cos x}} = \frac{\sin x}{1 + \cos x} = \frac{1 - \cos x}{\sin x}$$

Relations between Three Angles Whose Sum Is 180° Let x, y, z be the angles.

$$\sin x + \sin y + \sin z = 4\cos\left(\frac{x}{2}\right)\cos\left(\frac{y}{2}\right)\cos\left(\frac{z}{2}\right)$$

$$\cos x + \cos y + \cos z = 4\sin\left(\frac{x}{2}\right)\sin\left(\frac{y}{2}\right)\sin\left(\frac{z}{2}\right) + 1$$

$$\sin x + \sin y - \sin z = 4\sin\left(\frac{x}{2}\right)\sin\left(\frac{y}{2}\right)\cos\left(\frac{z}{2}\right)$$

$\sin^2 x + \sin^2 y + \sin^2 z = 2\cos x\cos y\cos z + 2$; $\tan x + \tan y + \tan z = \tan x\tan y\tan z$; $\sin 2x + \sin 2y + \sin 2z = 4\sin x\sin y\sin z$.

INVERSE TRIGONOMETRIC FUNCTIONS

$y = \sin^{-1} x = \arcsin x$ is the angle y whose sine is x.

Example $y = \sin^{-1}\frac{1}{2}$, y is 30°.

The complete solution of the equation $x = \sin y$ is $y = (-1)^n\sin^{-1} x + n(180°)$, $-\pi/2 \le \sin^{-1} x \le \pi/2$ where $\sin^{-1} x$ is the principal value of the angle whose sine is x. The range of principal values of the $\cos^{-1} x$ is $0 \le \cos^{-1} x \le \pi$ and $-\pi/2 \le \tan^{-1} x \le \pi/2$. If these restrictions are allowed to hold, the following formulas result:

$$\sin^{-1} x = \cos^{-1} \sqrt{1-x^2} = \tan^{-1} \frac{x}{\sqrt{1-x^2}} = \cot^{-1} \frac{\sqrt{1-x^2}}{x}$$

$$= \sec^{-1} \frac{1}{\sqrt{1-x^2}} = \csc^{-1} \frac{1}{x} = \frac{\pi}{2} - \cos^{-1} x$$

$$\cos^{-1} x = \sin^{-1} \sqrt{1-x^2} = \tan^{-1} \frac{\sqrt{1-x^2}}{x}$$

$$= \cot^{-1} \frac{x}{\sqrt{1-x^2}} = \sec^{-1} \frac{1}{x}$$

$$= \csc^{-1} \frac{1}{\sqrt{1-x^2}} = \frac{\pi}{2} - \sin^{-1} x$$

$$\tan^{-1} x = \sin^{-1} \frac{x}{\sqrt{1-x^2}} = \cos^{-1} \frac{1}{\sqrt{1+x^2}}$$

$$= \cot^{-1} \frac{1}{x} = \sec^{-1} \sqrt{1+x^2} = \csc^{-1} \frac{\sqrt{1+x^2}}{x}$$

RELATIONS BETWEEN ANGLES AND SIDES OF TRIANGLES

Solutions of Triangles (Fig. 3-43) Let a, b, c denote the sides and α, β, γ the angles opposite the sides in the triangle. Let $2s = a + b + c$, A = area, r = radius of the inscribed circle, R = radius of the circumscribed circle, and h = altitude. In any triangle $\alpha + \beta + \gamma = 180°$.

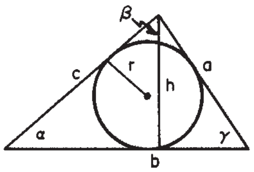

FIG. 3-43 Triangle.

Law of Sines $\sin \alpha / a = \sin \beta / b = \sin \gamma / c$.

Law of Tangents

$$\frac{a+b}{a-b} = \frac{\tan \frac{1}{2}(\alpha+\beta)}{\tan \frac{1}{2}(\alpha-\beta)}; \quad \frac{b+c}{b-c} = \frac{\tan \frac{1}{2}(\beta+\gamma)}{\tan \frac{1}{2}(\beta-\gamma)}; \quad \frac{a+c}{a-c} = \frac{\tan \frac{1}{2}(\alpha+\gamma)}{\tan \frac{1}{2}(\alpha-\gamma)}$$

Law of Cosines $a^2 = b^2 + c^2 - 2bc \cos \alpha$; $b^2 = a^2 + c^2 - 2ac \cos \beta$; $c^2 = a^2 + b^2 - 2ab \cos \gamma$.

Other Relations In this subsection, where appropriate, two more formulas can be generated by replacing a by b, b by c, c by a, α by β, β by γ, and γ by α. $\cos \alpha = (b^2 + c^2 - a^2)/2bc$; $a = b \cos \gamma + c = \cos \beta$; $\sin \alpha = (2/bc) \sqrt{s(s-a)(s-b)(s-c)}$;

$$\sin\left(\frac{\alpha}{2}\right) = \sqrt{\frac{(s-b)(s-c)}{bc}}; \quad \cos\left(\frac{\alpha}{2}\right) = \sqrt{\frac{s(s-a)}{bc}}; \quad A = \frac{1}{2} bh$$

$$= \frac{1}{2} ab \sin \gamma = \frac{a^2 \sin \beta \sin \gamma}{2 \sin \alpha} = \sqrt{s(s-a)(s-b)(s-c)} = rs$$

where $$r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}}$$

$$R = a/(2 \sin \alpha) = abc/4A; \; h = c \sin a = a \sin \gamma = 2rs/b.$$

Example $a = 5$, $b = 4$, $\alpha = 30°$. Use the law of sines. $0.5/5 = \sin \beta/4$, $\sin \beta = \frac{2}{5}$, $\beta = 23°35'$, $\gamma = 126°25'$. So $c = \sin 126°25' / \frac{1}{10} = 10(.8047) = 8.05$.

The relations given here suffice to solve any triangle. One method for each triangle is given.

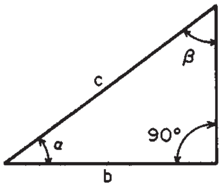

FIG. 3-44 Right triangle.

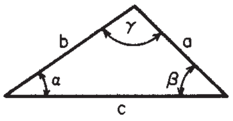

FIG. 3-45 Oblique triangle.

Right Triangle (Fig. 3-44) Given one side and any acute angle α or any two sides, the remaining parts can be obtained from the following formulas:

$$a = \sqrt{(c+b)(c-b)} = c \sin \alpha = b \tan \alpha$$

$$b = \sqrt{(c+a)(c-a)} = c \cos \alpha = a \cot \alpha$$

$$c = \sqrt{a^2 \pm b^2}, \; \sin \alpha = \frac{a}{c}, \; \cos \alpha = \frac{b}{c}, \; \tan \alpha = \frac{a}{b}, \; \beta = 90° - \alpha$$

$$A = \frac{1}{2} ab = \frac{a^2}{2 \tan \alpha} = \frac{b^2 \tan \alpha}{2} = \frac{c^2 \sin 2\alpha}{4}$$

Oblique Triangles (Fig. 3-45) There are four possible cases.

1. Given b, c and the included angles α,

$$\frac{1}{2}(\beta+\gamma) = 90° - \frac{1}{2}\alpha; \; \tan \frac{1}{2}(\beta-\gamma) = \frac{b-c}{b+c} \tan \frac{1}{2}(\beta+\gamma)$$

$$\beta = \frac{1}{2}(\beta+\gamma) + \frac{1}{2}(\beta-\gamma); \; \gamma = \frac{1}{2}(\beta+\gamma) - \frac{1}{2}(\beta-\gamma); \; a = \frac{b \sin \alpha}{\sin \beta}$$

2. Given the three sides a, b, c, $s = \frac{1}{2}(a+b+c)$;

$$r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}}$$

$$\tan \frac{1}{2}\alpha = \frac{r}{s-a}; \; \tan \frac{1}{2}\beta = \frac{r}{s-b}; \; \tan \frac{1}{2}\gamma = \frac{r}{s-c}$$

3. Given any two sides a, c and an angle opposite one of them α, $\sin \gamma = (c \sin \alpha)/a$; $\beta = 180° - a - \gamma$; $b = (a \sin \beta)/(\sin \alpha)$. There may be two solutions here. γ may have two values γ_1, γ_2; $\gamma_1 < 90°$, $\gamma_2 = 180° - \gamma_1 > 90°$. If $\alpha + \gamma_2 > 180°$, use only γ_1. This case may be *impossible* if $\sin \gamma > 1$.

4. Given any side c and two angles α and β, $\gamma = 180° - \alpha - \beta$; $a = (c \sin \alpha)/(\sin \gamma)$; $b = (c \sin \beta)/(\sin \gamma)$.

HYPERBOLIC TRIGONOMETRY

The hyperbolic functions are certain combinations of exponentials e^x and e^{-x}.

$$\cosh x = \frac{e^x + e^{-x}}{2}; \; \sinh x = \frac{e^x - e^{-x}}{2}; \; \tanh x = \frac{\sinh x}{\cosh x} = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

$$\coth x = \frac{e^x + e^{-x}}{e^x - e^{-x}} = \frac{1}{\tanh x} = \frac{\cosh x}{\sinh x}; \; \operatorname{sech} x = \frac{1}{\cosh x} = \frac{2}{e^x + e^{-x}};$$

$$\operatorname{csch} x = \frac{1}{\sinh x} = \frac{2}{e^x - e^{-x}}$$

Fundamental Relationships $\sinh x + \cosh x = e^x$; $\cosh x - \sinh x = e^{-x}$; $\cosh^2 x - \sinh^2 x = 1$; $\operatorname{sech}^2 x + \tanh^2 x = 1$; $\coth^2 x - \operatorname{csch}^2 x = 1$; $\sinh 2x = 2 \sinh x \cosh x$; $\cosh 2x = \cosh^2 x + \sinh^2 x = 1 + 2 \sinh^2 x = 2 \cosh^2 x - 1$. $\tanh 2x = (2 \tanh x)/(1 + \tanh^2 x)$; $\sinh (x \pm y) = \sinh x \cosh y \pm \cosh x \sinh y$; $\cosh (x \pm y) = \cosh x \cosh y \pm \sinh x \sinh y$; $2 \sinh^2 x/2 = \cosh x - 1$; $2 \cosh^2 x/2 = \cosh x + 1$; $\sinh(-x) = -\sinh x$; $\cosh(-x) = \cosh x$; $\tanh(-x) = -\tanh x$.

When $u = a \cosh x$, $v = a \sinh x$, then $u^2 - v^2 = a^2$; which is the equation for a hyperbola. In other words, the hyperbolic functions in the parametric equations $u = a \cosh x$, $v = a \sinh x$ have the same relation to the hyperbola $u^2 - v^2 = a^2$ that the equations $u = a \cos \theta$, $v = a \sin \theta$ have to the circle $u^2 + v^2 = a^2$.

Inverse Hyperbolic Functions If $x = \sinh y$, then y is the inverse hyperbolic sine of x written $y = \sinh^{-1} x$ or arcsinh x. $\sinh^{-1} x = \log_e (x + \sqrt{x^2 + 1})$

$$\cosh^{-1} x = \log_e (x + \sqrt{x^2 + 1});\ \tanh^{-1} x = \frac{1}{2} \log_e \frac{1 + x}{1 - x};$$

$$\coth^{-1} x = \frac{1}{2} \log_e \frac{x + 1}{x - 1};\ \text{sech}^{-1}\, x = \log_e \left(\frac{1 + \sqrt{1 - x^2}}{x}\right);$$

$$\text{csch}^{-1} = \log_e \left(\frac{1 + \sqrt{1 + x^2}}{x}\right)$$

Magnitude of the Hyperbolic Functions $\cosh x \geq 1$ with equality only for $x = 0$; $-\infty < \sinh x < \infty$; $-1 < \tanh x < 1$. $\cosh x \sim e^x/2$ as $x \to \infty$; $\sinh x \to e^x/2$ as $x \to \infty$.

APPROXIMATIONS FOR TRIGONOMETRIC FUNCTIONS

For small values of θ (θ measured in radians) $\sin \theta \approx \theta$, $\tan \theta \approx \theta$; $\cos \theta \approx 1 - (\theta^2/2)$. The following relations actually hold: $\sin \theta < \theta < \tan \theta$; $\cos \theta < \sin \theta/\theta < 1$; $\theta \sqrt{1 - \theta^2} < \sin \theta < \theta$; $\cos \theta < \theta/\tan \theta < 1$;

$$\theta \left(1 - \frac{\theta^2}{2}\right) < \sin \theta < \theta \text{ and } \theta < \tan \theta < \frac{\theta}{\sqrt{1 - \theta^2}}$$

The behavior ratio of the functions as $\theta \to 0$ is given by the following:

$$\lim_{\theta \to 0} \sin \theta/\theta = 1;\ \sin \theta/\tan \theta = 1.$$

DIFFERENTIAL AND INTEGRAL CALCULUS

REFERENCES: 114, 158, 260, 261, 274, 282, 296. See also "General References: References for General and Specific Topics—Advanced Calculus." For computer evaluations of the calculus described here, see Refs. 68, 299.

DIFFERENTIAL CALCULUS

An Example of Functional Notation Suppose that a storage warehouse of 16,000 ft^3 is required. The construction costs per square foot are \$10, \$3, and \$2 for walls, roof, and floor respectively. What are the minimum cost dimensions? Thus, with h = height, x = width, and y = length, the respective costs are

$$\text{Walls} = 2 \times 10hy + 2 \times 10hx = 20h(y + x)$$

$$\text{Roof} = 3xy$$

$$\text{Floor} = 2xy$$

$$\text{Total cost} = 2xy + 3xy + 20h(x + y) = 5xy + 20h(x + y) \tag{3-1}$$

and the restriction

$$\text{Total volume} = xyh \tag{3-2}$$

Solving for h from Eq. (3-2),

$$h = \text{volume}/xy = 16{,}000/xy \tag{3-3}$$

$$\text{Cost} = 5xy + \frac{320{,}000}{xy} (y + x) = 5xy + 320{,}000 \left(\frac{1}{x} + \frac{1}{y}\right) \tag{3-4}$$

In this form it can be shown that the minimum cost will occur for $x = y$; therefore

$$\text{Cost} = 5x^2 + 640{,}000\ (1/x)$$

By evaluation, the smallest cost will occur when $x = 40$.

$$\text{Cost} = 5(1600) + 640{,}000/40 = \$24{,}000$$

The dimensions are then $x = 40$ ft, $y = 40$ ft, $h = 16{,}000/(40 \times 40) = 10$ ft. Symbolically, the original cost relationship is written

$$\text{Cost} = f(x, y, h) = 5xy + 20h(y + x)$$

and the volume relation

$$\text{Volume} = g(x, y, h) = xyh = 16{,}000$$

In terms of the derived general relationships (3-1) and (3-2), x, y, and h are **independent variables—**cost and volume, **dependent variables.** That is, the cost and volume become fixed with the specification of dimensions. However, corresponding to the given restriction of the problem, relative to volume, the function $g(x, y, z) = xyh$ becomes a constraint function. In place of three independent and two dependent variables the problem reduces to two independent (volume has been constrained) and two dependent as in functions (3-3) and (3-4). Further, the requirement of minimum cost reduces the problem to three dependent variables (x, y, h) and no **degrees of freedom,** that is, freedom of independent selection.

Limits The limit of function $f(x)$ as x approaches a (a is finite or else x is said to increase without bound) is the number N.

$$\lim_{x \to a} f(x) = N$$

This states that $f(x)$ can be calculated as close to N as desirable by making x sufficiently close to a. This does not put any restriction on $f(x)$ when $x = a$. Alternatively, for any given positive number ε, a number δ can be found such that $0 < |a - x| < \delta$ implies that $|N - f(x)| < \varepsilon$.

The following operations with limits (when they exist) are valid:

$$\lim_{x \to a} bf(x) = b \lim_{x \to a} f(x)$$

$$\lim_{x \to a} [f(x) + g(x)] = \lim_{x \to a} f(x) + \lim_{x \to a} g(x)$$

$$\lim_{x \to a} [f(x)g(x)] = \lim_{x \to a} f(x) \cdot \lim_{x \to a} g(x)$$

$$\lim_{x \to a} \frac{f(x)}{g(x)} = \frac{\lim_{x \to a} f(x)}{\lim_{x \to a} g(x)} \quad \text{if} \quad \lim_{x \to a} g(x) \neq 0$$

Continuity A function $f(x)$ is continuous at the point $x = a$ if

$$\lim_{h \to 0} [f(a + h) - f(a)] = 0$$

Rigorously, it is stated $f(x)$ is continuous at $x = a$ if for any positive ε there exists a $\delta > 0$ such that $|f(a + h) - f(a)| < \varepsilon$ for all x with $|x - a| < \delta$. For example, the function $(\sin x)/x$ is not continuous at $x = 0$ and therefore is said to be discontinuous. Discontinuities are classified into three types:

1. Removable $\quad y = \sin x/x \quad$ at $x = 0$
2. Infinite $\quad y = 1/x \quad$ at $x = 0$
3. Jump $\quad y = 10/(1 + e^{1/x})$ at $x = 0^+$ $\ y = 0^+$
   $x = 0$ $\ y = 0$
   $x = 0^-$ $\ y = 10$

Derivative The function $f(x)$ has a derivative at $x = a$, which can be denoted as $f'(a)$, if

$$\lim_{h \to 0} \frac{f(a + h) - f(a)}{h}$$

exists. This implies continuity at $x = a$. Conversely, a function may be continuous but not have a derivative. The derivative function is

$$f'(x) = \frac{df}{dx} = \lim_{h \to 0} \frac{f(x + h) - f(x)}{h}$$

Differentiation Define $\Delta y = f(x + \Delta x) - f(x)$. Then dividing by Δx

$$\frac{\Delta y}{\Delta x} = \frac{f(x + \Delta x) - f(x)}{\Delta x}$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Call $\lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \frac{dy}{dx}$

then $\frac{dy}{dx} = \lim_{\Delta x \to 0} \frac{f(x + \Delta x) - f(x)}{\Delta x}$

Example Find the derivative of $y = \sin x$.

$$\frac{dy}{dx} = \lim_{\Delta x \to 0} \frac{\sin(x + \Delta x) - \sin(x)}{\Delta x}$$

$$= \lim_{\Delta x \to 0} \frac{\sin x \cos \Delta x + \sin \Delta x \cos x - \sin x}{\Delta x}$$

$$= \lim_{\Delta x \to 0} \frac{\sin x(\cos \Delta x - 1)}{\Delta x} + \lim_{\Delta x \to 0} \frac{\sin \Delta x \cos x}{\Delta x}$$

$$= \cos x \text{ since } \lim_{\Delta x \to 0} \frac{\sin \Delta x}{\Delta x} = 1$$

Differential Operations The following differential operations are valid: $f, g, \ldots$ are differentiable functions of x, c is a constant; e is the base of the natural logarithms.

$$\frac{dc}{dx} = 0 \quad (3\text{-}5)$$

$$\frac{dx}{dx} = 1 \quad (3\text{-}6)$$

$$\frac{d}{dx}(f + g) = \frac{df}{dx} + \frac{dg}{dx} \quad (3\text{-}7)$$

$$\frac{d}{dx}(f \times g) = f\frac{dg}{dx} + g\frac{df}{dx} \quad (3\text{-}8)$$

$$\frac{dy}{dx} = \frac{1}{dx/dy} \quad \text{if} \quad \frac{dx}{dy} \neq 0 \quad (3\text{-}9)$$

$$\frac{d}{dx} f^n = nf^{n-1}\frac{df}{dx} \quad (3\text{-}10)$$

$$\frac{d}{dx}\left(\frac{f}{g}\right) = \frac{g(df/dx) - f(dg/dx)}{g^2} \quad (3\text{-}11)$$

$$\frac{df}{dx} = \frac{df}{dv} \times \frac{dv}{dx} \quad \text{(chain rule)} \quad (3\text{-}12)$$

$$\frac{df^g}{dx} = gf^{g-1}\frac{df}{dx} + f^g \ln f \frac{dg}{dx} \quad (3\text{-}13)$$

$$\frac{da^x}{dx} = (\ln a)\, a^x \quad (3\text{-}14)$$

Example Derive dy/dx for $x^2 + y^3 = x + xy + A$.

Here $\frac{d}{dx}x^2 + \frac{d}{dx}y^3 = \frac{d}{dx}x + \frac{d}{dx}xy + \frac{d}{dx}A$

$$2x + 3y^2\frac{dy}{dx} = 1 + y + x\frac{dy}{dx} + 0$$

by rules (3-10), (3-10), (3-6), (3-8), and (3-5) respectively.

Thus $\frac{dy}{dx} = \frac{2x - 1 - y}{x - 3y^2}$

Differentials

$$de^x = e^x\, dx \quad (3\text{-}15a)$$

$$d(a^x) = a^x \log a\, dx \quad (3\text{-}15b)$$

$$d \ln x = (1/x)\, dx \quad (3\text{-}16)$$

$$d \log x = (\log e/x)dx \quad (3\text{-}17)$$

$$d \sin x = \cos x\, dx \quad (3\text{-}18)$$

$$d \cos x = -\sin x\, dx \quad (3\text{-}19)$$

$$d \tan x = \sec^2 x\, dx \quad (3\text{-}20)$$

$$d \sec x = \tan x \sec x\, dx \quad (3\text{-}22)$$

$$d \csc x = -\cot x \csc x\, dx \quad (3\text{-}23)$$

$$d \sin^{-1} x = (1 - x^2)^{-1/2}\, dx \quad (3\text{-}24)$$

$$d \cos^{-1} x = -(1 - x^2)^{-1/2}\, dx \quad (3\text{-}25)$$

$$d \tan^{-1} x = (1 + x^2)^{-1}\, dx \quad (3\text{-}26)$$

$$d \cot^{-1} x = -(1 + x^2)^{-1}\, dx \quad (3\text{-}27)$$

$$d \sec^{-1} x = x^{-1}(x^2 - 1)^{-1/2}\, dx \quad (3\text{-}28)$$

$$d \csc^{-1} x = -x^{-1}(x^2 - 1)^{-1/2}\, dx \quad (3\text{-}29)$$

$$d \sinh x = \cosh x\, dx \quad (3\text{-}30)$$

$$d \cosh x = \sinh x\, dx \quad (3\text{-}31)$$

$$d \tanh x = \text{sech}^2 x\, dx \quad (3\text{-}32)$$

$$d \coth x = -\text{csch}^2 x\, dx \quad (3\text{-}33)$$

$$d\, \text{sech}\, x = -\text{sech}\, x \tanh x\, dx \quad (3\text{-}34)$$

$$d\, \text{csch}\, x = -\text{csch}\, x \coth x\, dx \quad (3\text{-}35)$$

$$d \sinh^{-1} x = (x^2 + 1)^{-1/2}\, dx \quad (3\text{-}36)$$

$$d \cosh^{-1} = (x^2 - 1)^{-1/2}\, dx \quad (3\text{-}37)$$

$$d \tanh^{-1} x = (1 - x^2)^{-1}\, dx \quad (3\text{-}38)$$

$$d \coth^{-1} x = -(x^2 - 1)^{-1}\, dx \quad (3\text{-}39)$$

$$d\, \text{sech}^{-1} x = -(1/x)(1 - x^2)^{-1/2}\, dx \quad (3\text{-}40)$$

$$d\, \text{csch}^{-1} x = -x^{-1}(x^2 + 1)^{-1/2}\, dx \quad (3\text{-}41)$$

Example Find dy/dx for $y = \sqrt{x} \cos(1 - x^2)$.

Using

$$\frac{dy}{dx} = \sqrt{x}\frac{d}{dx}\cos(1 - x^2) + \cos(1 - x^2)\frac{d}{dx}\sqrt{x} \quad (3\text{-}8)$$

$$\frac{d}{dx}\cos(1 - x^2) = -\sin(1 - x^2)\frac{d}{dx}(1 - x^2) \quad (3\text{-}19)$$

$$= -\sin(1 - x^2)(0 - 2x) \quad (3\text{-}5), (3\text{-}10)$$

$$\frac{d\sqrt{x}}{dx} = \frac{1}{2}x^{-1/2} \quad (3\text{-}10)$$

$$\frac{dy}{dx} = 2x^{3/2}\sin(1 - x^2) + \frac{1}{2}x^{-1/2}\cos(1 - x^2)$$

Example Find the derivative of $\tan x$ with respect to $\sin x$.

$$v = \sin x$$

$$y = \tan x$$

Using

$$\frac{d \tan x}{d \sin x} = \frac{dy}{dv} = \frac{dy}{dx}\frac{dx}{dv} \quad (3\text{-}12)$$

$$= \frac{d \tan x}{dx} \frac{1}{\frac{d \sin x}{dx}} \quad (3\text{-}9)$$

$$= \sec^2 x/\cos x \quad (3\text{-}18), (3\text{-}20)$$

Very often in experimental sciences and engineering functions and their derivatives are available only through their numerical values. In particular, through measurements we may know the values of a function and its derivative only at certain points. In such cases the preceding operational rules for derivatives, including the chain rule, can be applied numerically.

Example Given the following table of values for differentiable functions f and g; evaluate the following quantities:

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

x	$f(x)$	$f'(x)$	$g(x)$	$g'(x)$
1	3	1	4	−4
3	0	2	4	7
4	−2	10	3	6

$$\frac{d}{dx}[f(x)+g(x)]|_{x=4} = f'(4)+g'(4) = 10+6 = 16$$

$$\left(\frac{f}{g}\right)'(1) = \frac{f'(1)g(1) - f(1)g'(1)}{[g(1)]^2} = \frac{1\cdot 4 - 3(-4)}{(-4)^2} = \frac{16}{16} = 1$$

Higher Differentials The first derivative of $f(x)$ with respect to x is denoted by f' or df/dx. The derivative of the first derivative is called the second derivative of $f(x)$ with respect to x and is denoted by f'', $f^{(2)}$, or d^2f/dx^2; and similarly for the higher-order derivatives.

Example Given $f(x) = 3x^3 + 2x + 1$, calculate all derivative values at $x = 3$.

$$\frac{df(x)}{dx} = 9x^2 + 2 \qquad x = 3, f'(3) = 9(9) + 2 = 83$$

$$\frac{d^2f(x)}{dx^2} = 18x \qquad x = 3, f''(3) = 18(3) = 54$$

$$\frac{d^3f(x)}{dx^3} = 18 \qquad x = 3, f'''(3) = 18$$

$$\frac{d^nf(x)}{dx^n} = 0 \qquad \text{for } n \geq 4$$

If $f'(x) > 0$ on (a, b), then f is increasing on (a, b). If $f'(x) < 0$ on (a, b), then f is decreasing on (a, b).

The graph of a function $y = f(x)$ is concave up if f' is increasing on (a, b); it is concave down if f' is decreasing on (a, b).

If $f''(x)$ exists on (a, b) and if $f''(x) > 0$, then f is concave up on (a, b). If $f''(x) < 0$, then f is concave down on (a, b).

An inflection point is a point at which a function changes the direction of its concavity.

Indeterminate Forms: L'Hospital's Theorem Forms of the type 0/0, ∞/∞, 0 × ∞, etc., are called indeterminates. To find the limiting values that the corresponding functions approach, L'Hospital's theorem is useful: If two functions $f(x)$ and $g(x)$ both become zero at $x = a$, then the limit of their quotient is equal to the limit of the quotient of their separate derivatives, if the limit exists or is + ∞ or − ∞.

Example Find $\lim_{n\to 0} \frac{\sin x}{x}$.

Here $$\lim_{x\to 0}\frac{\sin x}{x} = \lim_{x\to 0}\frac{d \sin x}{dx} = \lim_{x\to 0}\frac{\cos x}{1} = 1$$

Example Find $\lim_{x\to\infty} \frac{(1.1)^x}{x^{1000}}$.

$$\lim_{x\to\infty}\frac{(1.1)^x}{x^{1000}} = \lim_{x\to\infty}\frac{d(1.1)^x}{dx^{1000}} = \lim_{x\to\infty}\frac{(\ln 1.1)(1.1)^x}{1000x^{999}}$$

Obviously $\lim_{x\to\infty}\frac{1.1^x}{x^{1000}} = \infty$ since repeated application of the rule will reduce the denominator to a finite number 1000! while the numerator remains infinitely large.

Example Find $\lim_{x\to\infty} x^3 e^{-x}$.

$$\lim_{x\to\infty} x^3 e^{-x} = \lim_{x\to\infty}\frac{x^3}{e^x} = \lim_{x\to\infty}\frac{6}{e^x} = 0$$

Example Find $\lim_{x\to 0} (1-x)^{1/x}$.

Let $$y = (1-x)^{1/x}$$

$$\ln y = (1/x)\ln(1-x)$$

$$\lim_{x\to 0}(\ln y) = \lim_{x\to 0}\frac{\ln(1-x)}{x} = -1$$

Therefore, $$\lim_{x\to 0} y = e^{-1}$$

Partial Derivative The abbreviation $z = f(x, y)$ means that z is a function of the two variables x and y. The derivative of z with respect to x, treating y as a constant, is called the partial derivative with respect to x and is usually denoted as $\partial z/\partial x$ or $\partial f(x, y)/\partial x$ or simply f_x. Partial differentiation, like full differentiation, is quite simple to apply. Conversely, the solution of partial differential equations is appreciably more difficult than that of differential equations.

Example Find $\partial z/\partial x$ and $\partial z/\partial y$ for $z = ye^{x^2} + xe^y$.

$$\frac{\partial z}{\partial x} = y\frac{\partial e^{x^2}}{\partial x} + e^y\frac{\partial x}{\partial x} \qquad \frac{\partial z}{\partial y} = e^{x^2}\frac{\partial y}{\partial y} + x\frac{\partial e^y}{\partial y}$$

$$= 2xye^{x^2} + e^y \qquad = e^{x^2} + xe^y$$

Order of Differentiation It is generally true that the order of differentiation is immaterial for any number of differentiations or variables provided the function and the appropriate derivatives are continuous. For $z = f(x, y)$ it follows:

$$\frac{\partial^3 f}{\partial y^2\,\partial x} = \frac{\partial^3 f}{\partial y\,\partial x\,\partial y} = \frac{\partial^3 f}{\partial x\,\partial y^2}$$

General Form for Partial Differentiation

1. Given $f(x, y) = 0$ and $x = g(t)$, $y = h(t)$.

Then $$\frac{df}{dt} = \frac{\partial f}{\partial x}\frac{dx}{dt} + \frac{\partial f}{\partial y}\frac{dy}{dt}$$

$$\frac{d^2f}{dt^2} = \frac{\partial^2 f}{\partial x^2}\left(\frac{dx}{dt}\right)^2 + 2\frac{\partial^2 f}{\partial x\,\partial y}\frac{dx}{dt}\frac{dy}{dt} + \frac{\partial^2 f}{\partial y^2}\left(\frac{dy}{dt}\right)^2 + \frac{\partial f}{\partial x}\frac{d^2x}{dt^2} + \frac{\partial f}{\partial y}\frac{d^2y}{dt^2}$$

Example Find df/dt for $f = xy$, $x = \rho \sin t$, $y = \rho \cos t$.

$$\frac{df}{dt} = \frac{\partial(xy)}{\partial x}\left(\frac{d\,\rho\sin t}{dt}\right) + \frac{\partial(xy)}{\partial y}\left(\frac{d\,\rho\cos t}{dt}\right)$$

$$= y(\rho\cos t) + x(-\rho\sin t)$$

$$= \rho^2\cos^2 t - \rho^2\sin^2 t$$

2. Given $f(x, y) = 0$ and $x = g(t, s)$, $y = h(t, s)$.

Then $$\frac{\partial f}{\partial t} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial t}$$

$$\frac{\partial f}{\partial s} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial x}$$

Differentiation of Composite Function

Rule 1. Given $f(x, y) = 0$, then $\frac{dy}{dx} = -\frac{\partial f/\partial x}{\partial f/\partial y}\left(\frac{\partial f}{\partial y} \neq 0\right)$.

Rule 2. Given $f(u) = 0$ where $u = g(x)$, then

$$\frac{df}{dx} = f'(u)\frac{du}{dx}$$

$$\frac{d^2f}{dx^2} = f''(u)\left(\frac{du}{dx}\right)^2 + f'(u)\frac{d^2u}{dx^2}$$

Example Find df/dx for $f = \sin^2 u$ and $u = \sqrt{1-x^2}$

$$\frac{df}{dx} = \frac{d\sin^2 u}{du}\frac{d\sqrt{1-x^2}}{dx}$$

$$= 2\sin u\cos u\left(\frac{1}{2}\right)(-2x)(1-x^2)^{-1/2}$$

$$= -2\frac{\sqrt{1-u^2}}{u}\sin u\cos u$$

Rule 3. Given $f(u) = 0$ where $u = g(x,y)$, then

$$\frac{\partial f}{\partial x} = f'(u)\frac{\partial u}{\partial x} \qquad \frac{\partial f}{\partial y} = f'(u)\frac{\partial u}{\partial y}$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

$$\frac{\partial^2 f}{\partial x^2} = f'' \left(\frac{\partial u}{\partial x}\right)^2 + f' \frac{\partial^2 u}{\partial x^2}$$

$$\frac{\partial^2 f}{\partial x\,\partial y} = f'' \frac{\partial u}{\partial x}\frac{\partial u}{\partial y} + f' \frac{\partial^2 u}{\partial x\,\partial y}$$

$$\frac{\partial^2 f}{\partial y^2} = f'' \left(\frac{\partial u}{\partial y}\right)^2 + f' \frac{\partial^2 u}{\partial y^2}$$

MULTIVARIABLE CALCULUS APPLIED TO THERMODYNAMICS

Many of the functional relationships needed in thermodynamics are direct applications of the rules of multivariable calculus. This section reviews those rules in the context of the needs of thermodynamics. These ideas were expounded in one of the classic books on chemical engineering thermodynamics.[151]

State Functions State functions depend only on the state of the system, not on past history or how one got there. If z is a function of two variables, x and y, then $z(x,y)$ is a state function, since z is known once x and y are specified. The differential of z is

$$dz = M\,dx + N\,dy$$

The line integral

$$\int_C (M\,dx + N\,dy)$$

is independent of the path in x-y space if and only if

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x} \qquad (3\text{-}42)$$

The total differential can be written as

$$dz = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy \qquad (3\text{-}43)$$

and the following condition guarantees path independence.

$$\frac{\partial}{\partial y}\left(\frac{\partial z}{\partial x}\right)_y = \frac{\partial}{\partial x}\left(\frac{\partial z}{\partial y}\right)_x$$

or

$$\frac{\partial^2 z}{\partial y\,\partial x} = \frac{\partial^2 z}{\partial x\,\partial y} \qquad (3\text{-}44)$$

Example Suppose z is constant and apply Eq. (3-43).

$$\left[0 = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy\right]_z$$

Rearrangement gives

$$\left(\frac{\partial z}{\partial x}\right)_y = -\left(\frac{\partial y}{\partial x}\right)_z \left(\frac{\partial z}{\partial y}\right)_x = -\frac{(\partial y/\partial x)_z}{(\partial y/\partial z)_x} \qquad (3\text{-}45)$$

Alternatively, divide Eq. (3-43) by dy when holding some other variable w constant to obtain

$$\left(\frac{\partial z}{\partial y}\right)_w = \left(\frac{\partial z}{\partial x}\right)_v \left(\frac{\partial x}{\partial y}\right)_w + \left(\frac{\partial z}{\partial y}\right)_x \qquad (3\text{-}46)$$

Also divide both numerator and denominator of a partial derivative by dw while holding a variable y constant to get

$$\left(\frac{\partial z}{\partial x}\right)_y = \frac{(\partial z/\partial w)_y}{(\partial x/\partial w)_y} = \left(\frac{\partial z}{\partial w}\right)_y \left(\frac{\partial w}{\partial x}\right)_y \qquad (3\text{-}47)$$

Themodynamic State Functions In thermodynamics, the state functions include the internal energy, U; enthalpy, H; and Helmholtz and Gibbs free energies, A and G, respectively, defined as follows:

$$H = U + p\,V$$
$$A = U - TS$$
$$G = H - TS = U + pV - TS = A + pV$$

S is the entropy, T the absolute temperature, p the pressure, and V the volume. These are also state functions, in that the entropy is specified once two variables (like T and p) are specified, for example. Likewise, V is specified once T and p are specified; it is therefore a state function.

All applications are for closed systems with constant mass. If a process is reversible and only p-V work is done, the first law and differentials can be expressed as follows.

$$dU = T\,dS - p\,dV$$
$$dH = T\,dS + V\,dp$$
$$dA = -S\,dT - p\,dV$$
$$dG = -S\,dT + V\,dp$$

Alternatively, if the internal energy is considered a function of S and V, then the differential is:

$$dU = \left(\frac{\partial U}{\partial S}\right)_V dS + \left(\frac{\partial U}{\partial V}\right)_S dV$$

This is the equivalent of Eq. (3-43) and gives the following definitions.

$$T = \left(\frac{\partial U}{\partial S}\right)_V, \quad p = -\left(\frac{\partial U}{\partial V}\right)_S$$

Since the internal energy is a state function, then Eq. (3-44) must be satisfied.

$$\frac{\partial^2 U}{\partial V\,\partial S} = \frac{\partial^2 U}{\partial S\,\partial V}$$

This is

$$\left(\frac{\partial T}{\partial V}\right)_S = -\left(\frac{\partial p}{\partial S}\right)_V$$

This is one of the Maxwell relations, and the other Maxwell relations can be derived in a similar fashion by applying Eq. (3-44).

$$\left(\frac{\partial T}{\partial p}\right)_S = \left(\frac{\partial V}{\partial S}\right)_p$$

$$\left(\frac{\partial S}{\partial V}\right)_T = \left(\frac{\partial p}{\partial T}\right)_V$$

$$\left(\frac{\partial S}{\partial p}\right)_T = -\left(\frac{\partial V}{\partial T}\right)_p$$

In process simulation it is necessary to calculate enthalpy as a function of state variables. This is done using the following formulas, derived from the above relations by considering S and H as functions of T and p.

$$dH = C_p\,dT + \left[V - T\left(\frac{\partial V}{\partial T}\right)_p\right] dp$$

Enthalpy differences are then given by the following formula.

$$H(T_2, p_2) - H(T_1, p_1) = \int_{T_1}^{T_2} C_p(T, p_1)\,dT + \int_{p_1}^{p_2} \left[V - T\left(\frac{\partial V}{\partial T}\right)_p\right]\Bigg|_{T_2,p} dp$$

The same manipulations can be done for internal energy as a function of T and V.

$$dU = C_V\,dT - \left[p + T\frac{(\partial V/\partial T)_p}{(\partial V/\partial p)_T}\right] dV$$

Partial Derivatives of All Thermodynamic Functions The various partial derivatives of the thermodynamic functions can be classified into six groups. In the general formulas below, the variables U, H, A, G or S are denoted by Greek letters, while the variables $V, T,$ or p are denoted by Latin letters.

Type I (3 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial a}{\partial b}\right)_c; \text{ Specific: } \left(\frac{\partial p}{\partial T}\right)_V$$

Eq. (3-45) gives

$$\left(\frac{\partial p}{\partial T}\right)_V = -\left(\frac{\partial V}{\partial T}\right)_p \left(\frac{\partial p}{\partial V}\right)_T = -\frac{(\partial V/\partial T)_p}{(\partial V/\partial p)_T}$$

Type II (30 possibilities)

$$\text{General: } \left(\frac{\partial \alpha}{\partial b}\right)_c; \text{ Specific: } \left(\frac{\partial G}{\partial T}\right)_V$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

The differential for G gives

$$\left(\frac{\partial G}{\partial T}\right)_V = -S + V\left(\frac{\partial p}{\partial T}\right)_V$$

Using the other equations for U, H, A, or S gives the other possibilities.

Type III (15 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial a}{\partial b}\right)_\alpha; \text{ Specific: } \left(\frac{\partial V}{\partial T}\right)_S$$

First expand the derivative using Eq. (3-45).

$$\left(\frac{\partial V}{\partial T}\right)_S = -\left(\frac{\partial S}{\partial T}\right)_V \left(\frac{\partial V}{\partial S}\right)_T = -\frac{(\partial S/\partial T)_V}{(\partial S/\partial V)_T}$$

Then evaluate the numerator and denominator as type II derivatives.

$$\left(\frac{\partial V}{\partial T}\right)_S = -\frac{\dfrac{C_V}{T}}{-\left(\dfrac{\partial V}{\partial T}\right)_p \left(\dfrac{\partial p}{\partial V}\right)_T} = \frac{C_V}{T}\frac{\left(\dfrac{\partial V}{\partial p}\right)_T}{\left(\dfrac{\partial V}{\partial T}\right)_p}$$

These derivatives are of importance for reversible, adiabatic processes (such as in an ideal turbine or compressor), since then the entropy is constant. An example is the Joule-Thomson coefficient.

$$\left(\frac{\partial T}{\partial p}\right)_H = \frac{1}{C_p}\left[-V + T\left(\frac{\partial V}{\partial T}\right)_p\right]$$

Type IV (30 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial \beta}\right)_c; \text{ Specific: } \left(\frac{\partial G}{\partial A}\right)_p$$

Use Eq. (3-47) to introduce a new variable.

$$\left(\frac{\partial G}{\partial A}\right)_p = \left(\frac{\partial G}{\partial T}\right)_p \left(\frac{\partial T}{\partial A}\right)_p = \frac{(\partial G/\partial T)_p}{(\partial A/\partial T)_p}$$

This operation has created two type II derivatives; by substitution we obtain

$$\left(\frac{\partial G}{\partial A}\right)_p = \frac{S}{S + p\,(\partial V/\partial T)_p}$$

Type V (60 possibilities)

$$\text{General: } \left(\frac{\partial \alpha}{\partial b}\right)_\beta; \text{ Specific: } \left(\frac{\partial G}{\partial p}\right)_A$$

Start from the differential for dG. Then we get

$$\left(\frac{\partial G}{\partial p}\right)_A = -S\left(\frac{\partial T}{\partial p}\right)_A + V$$

The derivative is type III and can be evaluated by using Eq. (3-45).

$$\left(\frac{\partial G}{\partial p}\right)_A = S\frac{(\partial A/\partial p)_T}{(\partial A/\partial T)_p} + V$$

The two type II derivatives are then evaluated.

$$\left(\frac{\partial G}{\partial p}\right)_A = \frac{Sp\,(\partial V/\partial p)_T}{S + p\,(\partial V/\partial T)_p} + V$$

These derivatives are also of interest for free expansions or isentropic changes.

Type VI (30 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial \beta}\right)_\gamma; \text{ Specific: } \left(\frac{\partial G}{\partial A}\right)_H$$

We use Eq. (3-47) to obtain two type V derivatives.

$$\left(\frac{\partial G}{\partial A}\right)_H = \frac{(\partial G/\partial T)_H}{(\partial A/\partial T)_H}$$

These can then be evaluated using the procedures for Type V derivatives.

INTEGRAL CALCULUS

Indefinite Integral If $f'(x)$ is the derivative of $f(x)$, an antiderivative of $f'(x)$ is $f(x)$. Symbolically, the indefinite integral of $f'(x)$ is

$$\int f'(x)\,dx = f(x) + c$$

where c is an arbitrary constant to be determined by the problem. By virtue of the known formulas for differentiation the following relationships hold (a is a constant):

$$\int (du + dv + dw) = \int du + \int dv + \int dw \tag{3-48}$$

$$\int a\,dv = a\int dv \tag{3-49}$$

$$\int v^n\,dv = \frac{v^{n+1}}{n+1} + c \quad (n \neq -1) \tag{3-50}$$

$$\int \frac{dv}{v} = \ln |v| + c \tag{3-51}$$

$$\int a^v\,dv = \frac{a^v}{\ln a} + c \tag{3-52}$$

$$\int e^v\,dv = e^v + c \tag{3-53}$$

$$\int \sin v\,dv = -\cos v + c \tag{3-54}$$

$$\int \cos v\,dv = \sin v + c \tag{3-55}$$

$$\int \sec^2 v\,dv = \tan v + c \tag{3-56}$$

$$\int \csc^2 v\,dv = -\cot v + c \tag{3-57}$$

$$\int \sec v \tan v\,dv = \sec v + c \tag{3-58}$$

$$\int \csc v \cot v\,dv = -\csc v + c \tag{3-59}$$

$$\int \frac{dv}{v^2 + a^2} = \frac{1}{a}\tan^{-1}\frac{v}{a} + c \tag{3-60}$$

$$\int \frac{dv}{\sqrt{a^2 - v^2}} = \sin^{-1}\frac{v}{a} + c \tag{3-61}$$

$$\int \frac{dv}{v^2 - a^2} = \frac{1}{2a}\ln\left|\frac{v-a}{v+a}\right| + c \tag{3-62}$$

$$\int \frac{dv}{\sqrt{v^2 \pm a^2}} = \ln |v + \sqrt{v^2 \pm a^2}| + c \tag{3-63}$$

$$\int \sec v\,dv = \ln(\sec v + \tan v) + c \tag{3-64}$$

$$\int \csc v\,dv = \ln(\csc v - \cot v) + c \tag{3-65}$$

Example Derive $\int a^v\,dv = (a^v/\ln a) + c$. By reference to the differentiation formula $da^v/dv = a^v \ln a$, or in the more usable form $d(a^v/\ln a) = a^v\,dv$, let $f' = a^v\,dv$; then $f = a^v/\ln a$ and hence $\int a^v\,dv = (a^v/\ln a) + c$.

Example Find $\int (3x^2 + e^x - 10)\,dx$ using Eq. (3-48). $\int (3x^2 + e^x - 10)\,dx = 3\int x^2\,dx + \int e^x\,dx - 10\int dx = x^3 + e^x - 10x + c$ (by Eqs. 3-50, 3-53).

Example Find $\int \frac{7x\,dx}{2 - 3x^2}$. Let $v = 2 - 3x^2$; $dv = -6x\,dx$

Thus

$$\int \frac{7x\,dx}{2 - 3x^2} = 7\int \frac{x\,dx}{2 - 3x^2} = -\frac{7}{6}\int \frac{-6x\,dx}{2 - 3x^2}$$

$$= -\frac{7}{6}\int \frac{dv}{v}$$

$$= -\frac{7}{6}\ln |v| + c$$

$$= -\frac{7}{6}\ln |2 - 3x^2| + c$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Example—Constant of Integration By definition the derivative of x^3 is $3x^2$, and x^3 is therefore the integral of $3x^2$. However, if $f = x^3 + 10$, it follows that $f' = 3x^2$, and $x^3 + 10$ is therefore also the integral of $3x^2$. For this reason the constant c in $\int 3x^2\,dx = x^3 + c$ must be determined by the problem conditions, i.e., the value of f for a specified x.

Methods of Integration In practice it is rare when generally encountered functions can be directly integrated. For example, the integrand in $\int \sqrt{\sin x}\,dx$ which appears quite simple has no elementary function whose derivative is $\sqrt{\sin x}$. In general, there is no explicit way of determining whether a particular function can be integrated into an elementary form. As a whole, integration is a trial-and-error proposition which depends on the effort and ingenuity of the practitioner. The following are general procedures which can be used to find the elementary forms of the integral when they exist. When they do not exist or cannot be found either from tabled integration formulas or directly, the only recourse is series expansion as illustrated later. Indefinite integrals cannot be solved numerically unless they are redefined as definite integrals (see "Definite Integral"), i.e., $F(x) = \int f(x)\,dx$, indefinite, whereas $F(x) = \int_a^x f(t)\,dt$, definite.

Direct Formula Many integrals can be solved by transformation in the integrand to one of the forms given previously.

Example Find $\int x^2\sqrt{3x^3 + 10}\,dx$. Let $v = 3x^3 + 10$ for which $dv = 9x^2\,dx$. Thus

$$\int x^2\sqrt{3x^3+10}\,dx = \int (3x^3+10)^{1/2}(x^2\,dx)$$

$$= \frac{1}{9}\int (3x^3+10)^{1/2}(9x^2\,dx)$$

$$= \frac{1}{9}\int v^{1/2}\,dv$$

$$= \frac{1}{9}\,\frac{v^{3/2}}{3/2} + c \qquad \text{[by Eq. (3-50)]}$$

$$= \frac{2}{27}(3x^3+10)^{3/2} + c$$

Trigonometric Substitution This technique is particularly well adapted to integrands in the form of radicals. For these the function is transformed into a trigonometric form. In the latter form they may be more easily recognizable relative to the identity formulas. These functions and their transformations are

$$\sqrt{x^2-a^2} \qquad \text{Let } x = a\sec\theta$$

$$\sqrt{x^2+a^2} \qquad \text{Let } x = a\tan\theta$$

$$\sqrt{a^2-x^2} \qquad \text{Let } x = a\sin\theta$$

Example Find $\int \frac{\sqrt{4-9x^2}}{x^2}\,dx$. Let $x = \frac{2}{3}\sin\theta$; then $dx = \frac{2}{3}\cos\theta\,d\theta$.

$$3\int \frac{\sqrt{(2/3)^2 - x^2}}{x^2}\,dx = 3\int \frac{2/3\sqrt{1-\sin^2\theta}}{(2/3)^2\sin^2\theta}\left(\frac{2}{3}\cos\theta\,d\theta\right)$$

$$= 3\int \frac{\cos^2\theta}{\sin^2\theta}\,d\theta$$

$$= 3\int \cot^2\theta\,d\theta$$

$$= -3\cot\theta - 3\theta + c \text{ by trigonometric transform}$$

$$= -\frac{\sqrt{4-9x^2}}{x} - 3\sin^{-1}\frac{3}{2}x + c \text{ in terms of } x$$

Algebraic Substitution Functions containing elements of the type $(a + bx)^{1/n}$ are best handled by the algebraic transformation $y^n = a + bx$.

Example Find $\int \frac{x\,dx}{(3+4x)^{1/4}}$. Let $3 + 4x = y^4$; then $4dx = 4y^3\,dy$ and

$$\int \frac{x\,dx}{(3+4x)^{1/4}} = \int \frac{\frac{y^4-3}{4}y^3\,dy}{y}$$

$$= \frac{1}{4}\int y^2(y^4-3)\,dy$$

$$= \frac{1}{4}\frac{y^7}{7} - \frac{3}{4}\frac{y^3}{3} + c$$

$$= \frac{1}{28}(3+4x)^{7/4} - \frac{1}{4}(3+4x)^{3/4} + c$$

General The number of possible transformations one might use are unlimited. No specific overall rules can be given. Success in handling integration problems depends primarily upon experience and ingenuity. The following example illustrates the extent to which alternative approaches are possible.

Example Find $\int \frac{dx}{e^x - 1}$. Let $e^x = y$; then $e^x\,dx = dy$ or $dx = 1/y\,dy$.

$$\int \frac{dx}{e^x-1} = \int \frac{(1/y)\,dy}{y-1} = \int \frac{dy}{y^2-y} = \ln\frac{y-1}{y} = \ln\frac{e^x-2}{e^x}$$

Partial Fractions Rational functions are of the type $f(x)/g(x)$ where $f(x)$ and $g(x)$ are polynomial expressions of degrees m and n respectively. If the degree of f is higher than g, perform the algebraic division—the remainder will then be at least one degree less than the denominator. Consider the following types:

Type 1 Reducible denominator to linear unequal factors. For example,

$$\frac{1}{x^3-x^2-4x+4} = \frac{1}{(x+2)(x-2)(x-1)}$$

$$= \frac{A}{x+2} + \frac{B}{x-2} + \frac{C}{x-1}$$

$$= \frac{A(x-2)(x-1) + B(x+2)(x-1) + C(x+2)(x-2)}{(x+2)(x-2)(x-1)}$$

$$= \frac{x^2(A+B+C) + x(-3A+B) + (2A-2B-4C)}{(x+2)(x-2)(x-1)}$$

Equate coefficients and solve for A, B, and C.

$$A + B + C = 0$$

$$-3A + B = 0$$

$$2A - 2B - 4C = 1$$

$$A = 1/12,\ B = 1/4,\ C = -1/3$$

$$\frac{1}{x^3-x^2-4x+4} = \frac{1}{12(x+2)} + \frac{1}{4(x-2)} - \frac{1}{3(x-1)}$$

Hence

$$\int \frac{dx}{x^3-x^2-4x+4} = \int \frac{dx}{12(x+2)} + \int \frac{dx}{4(x-2)} - \int \frac{dx}{3(x-1)}$$

Parts An extremely useful formula for integration is the relation

$$d(uv) = u\,dv + v\,du$$

and

$$uv = \int u\,dv + \int v\,du$$

or

$$\int u\,dv = uv - \int v\,du$$

No general rule for breaking an integrand can be given. Experience alone limits the use of this technique. It is particularly useful for trigonometric and exponential functions.

Example Find $\int xe^x\,dx$. Let

$$u = x \qquad \text{and} \qquad dv = e^x\,dx$$

$$du = dx \qquad\qquad v = e^x$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Therefore $$\int xe^x\,dx = xe^x - \int e^x\,dx$$
$$= xe^x - e^x + c$$

Example Find $\int e^x \sin x\,dx$. Let

$$u = e^x \qquad dv = \sin x\,dx$$
$$du = e^x\,dx \qquad v = -\cos x$$
$$\int e^x \sin x\,dx = -e^x \cos x + \int e^x \cos x\,dx$$

Again $$u = e^x \qquad dv = \cos x\,dx$$
$$du = e^x\,dx \qquad v = \sin x$$
$$\int e^x \sin x\,dx = -e^x \cos x + e^x \sin x - \int e^x \sin x\,dx + c$$
$$= (e^x/2)(\sin x - \cos x) + \frac{c}{2}$$

Series Expansion When an explicit function cannot be found, the integration can sometimes be carried out by a series expansion.

Example Find $\int e^{-x^2}\,dx$. Since

$$e^{-x^2} = 1 - x^2 + \frac{x^4}{2!} - \frac{x^6}{3!} + \cdots$$
$$\int e^{-x^2}\,dx = \int dx - \int x^2\,dx + \int \frac{x^4}{2!}\,dx - \int \frac{x^6}{3!}\,dx + \cdots$$
$$= x - \frac{x^3}{3} + \frac{x^5}{5.2!} - \frac{x^7}{7.3!} + \cdots \qquad \text{for all } x$$

Definite Integral The concept and derivation of the definite integral are completely different from those for the indefinite integral. These are by definition different types of operations. However, the formal operation $\int$ as it turns out treats the integrand in the same way for both.

Consider the function $f(x) = 10 - 10e^{-2x}$. Define $x_1 = a$ and $x_n = b$, and suppose it is desirable to compute the area between the curve and the coordinate axis $y = 0$ and bounded by $x_1 = a$, $x_n = b$. Obviously, by a sufficiently large number of rectangles this area could be approximated as closely as desired by the formula

$$\sum_{i=1}^{n-1} f(\xi_i)(x_{i+1} - x_i) = f(\xi_1)(x_2 - a) + f(\xi_2)(x_3 - x_2)$$
$$+ \cdots + f(\xi_{n-1})(b - x_{n-1}) \qquad x_{i-1} \le \xi_{i-1} \le x_i$$

The definite integral of $f(x)$ is defined as

$$\int_a^b f(x)\,dx = \lim_{n\to\infty} \sum_{i=1}^{n} f(\xi_i)(x_{i+1} - x_i)$$

where the points $x_1, x_2, \ldots, x_n$ are equally spaced. For a rigorous definition of the definite integral the references should be consulted.

Thus, the value of a definite integral depends on the limits a, b, and any selected variable coefficients in the function but not on the dummy variable of integration x. Symbolically

$$F(x) = \int f(x)\,dx \qquad \text{indefinite integral where } dF/dx = f(x)$$

or $$F(a, b) = \int_a^b f(x)\,dx \qquad \text{definite integral}$$

$$F(\alpha) = \int_a^b f(x, \alpha)\,dx$$

There are certain restrictions of the integration definition, "The function $f(x)$ must be continuous in the finite interval (a, b) with at most a finite number of finite discontinuities," which must be observed before integration formulas can be generally applied. Two of these restrictions give rise to so-called **improper integrals** and require special handling. These occur when

1. The limits of integration are not both finite, i.e., $\int_0^\infty e^{-x}\,dx$.
2. The function becomes infinite within the interval of integration, i.e.,

$$\int_0^1 \frac{1}{\sqrt{x}}\,dx$$

Techniques for determining when integration is valid under these conditions are available in the references. However, the following simplified rules will, in general, serve as a guide for most practical applications.

Rule 1 For the integral

$$\int_0^\infty \frac{\phi(x)}{x^n}\,dx$$

if $\phi(x)$ is bounded, the integral will converge for $n > 1$ and not converge for $n \le 1$.

It is easily seen that $\int_0^\infty e^{-x}\,dx$ converges by noting $1/x^2 > 1/e^x > 0$ for large x.

Rule 2 For the integral

$$\int_a^b \frac{\phi(x)}{(a - x)^n}\,dx,$$

if $\phi(x)$ is bounded, the integral will converge for $n < 1$ and diverge for $n \ge 1$. Thus

$$\int_0^1 \frac{1}{\sqrt{x}}\,dx$$

will converge (exist) since ½ = $n < 1$.

Properties The fundamental theorem of calculus states

$$\int_a^b f(x)\,dx = F(b) - F(a)$$

where $$dF(x)/dx = f(x)$$

Other properties of the definite integral are

$$\int_a^b c[f(x)\,dx] = c\int_a^b f(x)\,dx$$
$$\int_a^b [f_1(x) + f_2(x)]\,dx = \int_a^b f_1(x)\,dx + \int_a^b f_2(x)\,dx$$
$$\int_a^b f(x)\,dx = -\int_b^a f(x)\,dx$$
$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx$$
$$\int_a^b f(x)\,dx = (b - a)f(\xi) \text{ for some } \xi \text{ in } (a, b)$$
$$\frac{\partial}{\partial b}\int_a^b f(x)\,dx = f(b)$$
$$\frac{\partial}{\partial a}\int_a^b f(x)\,dx = -f(a)$$
$$\frac{dF(\alpha)}{d\alpha} = \int_a^b \frac{\partial f(x, \alpha)}{\partial \alpha}\,dx \text{ if } a \text{ and } b \text{ are constant}$$
$$\int_a^b dx \int_c^d f(x, \alpha)\,d\alpha = \int_c^d d\alpha \int_a^b f(x, \alpha)\,dx \tag{3-66}$$

when $F(x) = \int_{a(x)}^{b(x)} f(x, y)\,dy$

the Leibniz rule gives

$$\frac{dF}{dx} = \frac{db}{dx} f[x, b(x)] - \frac{da}{dx} f[x, a(x)] + \int_{a(x)}^{b(x)} \frac{\partial f}{\partial x}\,dy$$

Example Find $\int_0^{\pi/2} \sin x\,dx$.

$$\int_0^{\pi/2} \sin x\,dx = [-\cos x]_0^{\pi/2} = -\left(\cos\frac{\pi}{2} - \cos 0\right) = 1$$

since $$-d\cos x/dx = \sin x$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Example Find $\int_0^2 \frac{dx}{(x-1)^2}$. Direct application of the formula would yield the incorrect value

$$\int_0^2 \frac{dx}{(x-1)^2} = \left[-\frac{1}{x-1}\right]_0^2 = -2$$

It should be noted that $f(x) = 1/(x-1)^2$ becomes unbounded as $x \to 1$ and by Rule 2 the integral diverges and hence is said not to exist.

Methods of Integration All the methods of integration available for the indefinite integral can be used for definite integrals. In addition, several others are available for the latter integrals and are indicated below.

Change of Variable This substitution is basically the same as previously indicated for indefinite integrals. However, for definite integrals, the limits of integration must also be changed: i.e., for $x = \phi(t)$,

$$\int_a^b f(x)\, dx = \int_{t_0}^{t_1} f[\phi(t)]\phi'(t)\, dt$$

where $t = t_0$ when $x = a$
$t = t_1$ when $x = b$

Example Find $\int_0^4 \sqrt{16 - x^2}\, dx$. Let

$$x = 4 \sin \theta \qquad (x = 0, \theta = 0)$$
$$dx = 4 \cos \theta\, d\theta \qquad (x = 4, \theta = \pi/2)$$

Then $$\int_0^4 \sqrt{16 - x^2}\, dx = 16 \int_0^{\pi/2} \cos^2 \theta\, d\theta = 16[\tfrac{1}{2}\theta + \tfrac{1}{4} \sin 2\theta]_0^{\pi/2} = 4\pi$$

Differentiation Here the application of the general rules for differentiating under the integral sign may be useful.

Example Find

$$\phi(\alpha) = \int_0^\infty \frac{e^{-\alpha x} \sin x}{x}\, dx \quad (\alpha > 0)$$

Since this is a continuous function of α, it may be differentiated under the integral sign

$$\frac{d\phi}{d\alpha} = -\int_0^\infty e^{-\alpha x} \sin x\, dx$$
$$= -1/(1 + \alpha^2)$$
$$\phi(\alpha) = -\tan^{-1} \alpha + c$$

and since $\phi(\alpha) \to 0$ as $\alpha \to \infty$,

$$c = \pi/2$$
$$\phi(\alpha) = -\tan^{-1} \alpha + \pi/2$$

Integration It is sometimes useful to generate a double integral to solve a problem. By this approach, the fundamental theorem indicated by Eq. (3-66) can be used.

Example Find $$\int_0^1 \frac{x^b - x^\alpha}{\ln x}\, dx$$

Consider $$\int_0^1 x^\alpha\, dx = \frac{1}{\alpha + 1} \quad (\alpha > -1)$$

Then multiplying both sides by $d\alpha$ and integrating between a and b,

$$\int_a^b d\alpha \int_0^1 x^\alpha\, dx = \int_a^b \frac{d\alpha}{\alpha + 1} = \ln \left|\frac{b+1}{a+1}\right|$$

But also

$$\int_a^b d\alpha \int_0^1 x^\alpha\, dx = \int_0^1 dx \int_a^b x^\alpha\, d\alpha = \int_0^1 \frac{x^b - x^\alpha}{\ln x}\, dx$$

Therefore $$\int_0^1 \frac{x^b - x^\alpha}{\ln x}\, dx = \ln \left|\frac{b+1}{a+1}\right|$$

Complex Variable Certain definite integrals can be evaluated by the technique of complex variable integration. This is described in the references for "Complex Variables."

Numerical Because of the property of definite integrals another method for obtaining their solution is available which cannot be applied to indefinite integrals. This involves a numerical approximation based on the previously outlined summation definition:

$$\lim_{n \to \infty} \sum_1^{n-1} f(\xi_i)(x_{i+1} - x_i) = \int_a^b f(x)\, dx$$

where $x_1 = a$ and $x_n = b$

Examples of this procedure are given in the subsection "Numerical Analysis and Approximate Methods."

INFINITE SERIES

References: 53, 126, 127, 163. For asymptotic series and asymptotic methods, see Refs. 51, 127.

DEFINITIONS

A succession of numbers or terms that are formed according to some definite rule is called a sequence. The indicated sum of the terms of a sequence is called a series. A series of the form $a_0 + a_1(x - c) + a_2(x - c)^2 + \cdots + a_n(x - c)^n + \cdots$ is called a power series.

Consider the sum of a finite number of terms in the geometric series (a special case of a power series).

$$S_n = a + ar + ar^2 + ar^3 + \cdots + ar^{n-1} \qquad (3\text{-}67)$$

For any number of terms n, the sum equals

$$S_n = a \frac{1 - r^n}{1 - r}$$

In this form, the geometric series is assumed finite.

In the form of Eq. (3-67), it can further be defined that the terms in the series be nonending and therefore an infinite series.

$$S = a + ar + ar^2 + \cdots + ar^n + \cdots \qquad (3\text{-}68)$$

However, the defined sum of the terms [Eq. (3-67)]

$$S_n = a \frac{1 - r^n}{1 - r} \qquad r \neq 1$$

while valid for any finite value of r and n now takes on a different interpretation. In this sense it is necessary to consider the limit of S_n as n increases indefinitely:

$$S = \lim_{n \to \infty} S_n$$
$$= a \lim_{n \to \infty} \frac{1 - r^n}{1 - r}$$

For this, it is stated the infinite series converges if the limit of S_n approaches a fixed finite value as n approaches infinity. Otherwise, the series is **divergent.**

On this basis an analysis of

$$S = a \lim_{n \to \infty} \frac{1 - r^n}{1 - r}$$

shows that if r is less than 1 but greater than -1, the infinite series is convergent. For values outside of the range $-1 < r < 1$, the series is divergent because the sum is not defined. The range $-1 < r < 1$ is called the **region of convergence.** (We assume $a \neq 0$.)

Consider the divergence of Eq. (3-68) when $r = -1$ and $+1$. For the former case $r = -1$,

$$S = a + a(-1) + a(-1)^2 + a(-1)^3 + \cdots + a(-1)^n + \cdots$$
$$= a - a + a - a + a - \cdots$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

and for which

$$S = a \lim_{n\to\infty} \frac{1 - r^n}{1 - r}$$

$$= a \lim_{n\to\infty} \frac{1 - (-1)^n}{1 + 1} \quad \text{undefined limit (if } a \neq 0)$$

Since the limit sum does not exist, the series is divergent. This is defined as a bounded or oscillating divergent series. Similarly for the value $r = +1$,

$$S = a + a(1) + a(1)^2 + a(1)^3 + \cdots + a(1)^n + \cdots$$

$$S = a + a + a + a + \cdots + a + \cdots \qquad (a \neq 0)$$

The series is also divergent but defined as an **unbounded divergent series.**

There are also two types of convergent series. Consider the new series

$$S = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots + (-1)^{n+1}\frac{1}{n} + \cdots \qquad \text{(3-69)}$$

It can be shown that the series (3-69) does converge to the value $S = \log 2$. However, if each term is replaced by its absolute value, the series becomes unbounded and therefore divergent (unbounded divergent):

$$S = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \cdots \qquad \text{(3-70)}$$

In this case the series (3-69) is defined as a conditionally convergent series. If the replacement series of absolute values also converges, the series is defined to converge absolutely.

Series (3-69) is further defined as an alternating series, while series (3-70) is referred to as a positive series.

OPERATIONS WITH INFINITE SERIES

1. The convergence or divergence of an infinite series is unaffected by the removal of a finite number of finite terms. This is a trivial theorem but useful to remember, especially when using the comparison test to be described in the subsection "Tests for Convergence and Divergence."

2. If a series is conditionally convergent, its sums can be made to have any arbitrary value by a suitable rearrangement of the series; it can in fact be made divergent or oscillatory (Riemann's theorem). This seemingly paradoxical theorem can be illustrated by the following example.

Example $S = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5} - \frac{1}{6} + \cdots$

The series is rearranged so that each positive term is followed by two negative terms:

$$t = 1 - \frac{1}{2} - \frac{1}{4} + \frac{1}{3} - \frac{1}{6} - \frac{1}{8} + \frac{1}{5} - \frac{1}{10} - \frac{1}{12} + \cdots$$

Define t_{3n} for the first $3n$ terms in the series

$$t_{3n} = \left(1 - \frac{1}{2}\right) - \frac{1}{4} + \left(\frac{1}{3} - \frac{1}{6}\right) - \frac{1}{8} + \cdots + \left(\frac{1}{2n-1} - \frac{1}{4n-2}\right) - \frac{1}{4n}$$

$$= \frac{1}{2} - \frac{1}{4} + \frac{1}{6} - \frac{1}{8} + \cdots + \frac{1}{4n-2} - \frac{1}{4n}$$

$$= \frac{1}{2}\left(1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots + \frac{1}{2n-1} - \frac{1}{2n}\right)$$

$$= \frac{1}{2} S_{2n}$$

where S_{2n} is the sum of the first $2n$ terms of the original series. Thus

$$\lim_{n\to\infty} t_{3n} = \lim_{n\to\infty} \frac{1}{2} S_{2n}$$

$$t = \frac{1}{2} S$$

and since $\lim t_{3n+2} = \lim t_{3n+1} = \lim t_{3n}$, it follows the sum of the series t is (½) S. Hence a rearrangement of the terms of an alternating series alters the sum of the series.

3. A series of positive terms, if convergent, has a sum independent of the order of its terms; but if divergent, it remains divergent however its terms are rearranged.

4. An oscillatory series can always be made to converge by grouping the terms in brackets.

Example Consider the series

$$1 - \frac{1}{2} + \frac{2}{3} - \frac{3}{4} + \frac{4}{5} - \frac{5}{6} + \cdots$$

which oscillates between the values 0.306 and 1.306. However, the series

$$\left(1 - \frac{1}{2}\right) + \left(\frac{2}{3} - \frac{3}{4}\right) + \left(\frac{4}{5} - \frac{5}{6}\right) + \cdots = \frac{1}{2} - \frac{1}{12} - \frac{1}{30} - \frac{1}{56} - \cdots \cong 0.306 \cdots$$

and

$$1 - \left(\frac{1}{2} - \frac{2}{3}\right) - \left(\frac{3}{4} - \frac{4}{5}\right) - \left(\frac{5}{6} - \frac{6}{7}\right) + \cdots = 1 + \frac{1}{6} + \frac{1}{20} + \frac{1}{42} + \cdots = 1.306 \cdots$$

5. A power series can be inverted, provided the first-degree term is not zero. Given

$$y = b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + \cdots$$

then $\quad x = B_1 y + B_2 y^2 + B_3 y^3 + B_4 y^4 + B_5 y^5 + B_6 y^6 + B_7 y^7 + \cdots$

where
$B_1 = 1/b_1$
$B_2 = -b_2/b_1^3$
$B_3 = (1/b_1^5)\,(2b_2^2 - b_1 b_3)$
$B_4 = (1/b_1^7)(5b_1 b_2 b_3 - b_1^2 b_4 - 5b_2^3)$

Additional coefficients are available in the references.

6. Two series may be added or subtracted term by term provided each is a convergent series. The joint sum is equal to the sum (or difference) of the individuals.

7. The sum of two divergent series can be convergent. Similarly, the sum of a convergent series and a divergent series must be divergent.

Example Given

$$\sum_{n=1}^{\infty}\left(\frac{1+n}{n^2}\right) = \frac{2}{1} + \frac{3}{4} + \frac{4}{9} + \frac{5}{16} + \cdots \qquad \text{(a divergent series)}$$

$$\sum_{n=1}^{\infty}\left(\frac{1-n}{n^2}\right) = -\frac{1}{4} - \frac{2}{9} - \frac{3}{16} + \cdots \qquad \text{(a divergent series)}$$

However, $$\sum\left(\frac{1+n}{n^2}\right) + \sum\left(\frac{1-n}{n^2}\right) = \sum\left(\frac{1+n+1-n}{n^2}\right)$$

$$= 2\sum\frac{1}{n^2} \qquad \text{(convergent)}$$

8. A power series may be integrated term by term to represent the integral of the function within an interval of the region of convergence. If $f(x) = a_0 + a_1 x + a_2 x^2 + \cdots$, then

$$\int_{x_1}^{x_2} f(x)\,dx = \int_{x_1}^{x_2} a_0\,dx + \int_{x_1}^{x_2} a_1 x\,dx + \int_{x_1}^{x_2} a_2 x^2\,dx + \cdots$$

9. A power series may be differentiated term by term and represents the function $df(x)/dx$ within the same region of convergence as $f(x)$.

TESTS FOR CONVERGENCE AND DIVERGENCE

In general, the problem of determining whether a given series will converge or not can require a great deal of ingenuity and resourcefulness. There is no all-inclusive test which can be applied to all series. As the only alternative, it is necessary to apply one or more of the developed theorems in an attempt to ascertain the convergence or divergence of the series under study. The following defined tests are given in relative order of effectiveness. For examples, see references on advanced calculus.

1. *Comparison Test.* A series will converge if the absolute value of each term (with or without a finite number of terms) is less than the corresponding term of a known convergent series. Similarly, a positive series is divergent if it is termwise larger than a known divergent series of positive terms.

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

2. *n*th-*Term Test.* A series is divergent if the nth term of the series does not approach zero as n becomes increasingly large.

3. *Ratio Test.* If the absolute ratio of the $(n + 1)$ term divided by the nth term as n becomes unbounded approaches

a. A number less than 1, the series is absolutely convergent
b. A number greater than 1, the series is divergent
c. A number equal to 1, the test is inconclusive

4. *Alternating-Series Leibniz Test.* If the terms of a series are alternately positive and negative and never increase in value, the absolute series will converge, provided that the terms tend to zero as a limit.

5. *Cauchy's Root Test.* If the nth root of the absolute value of the nth term, as n becomes unbounded, approaches

a. A number less than 1, the series is absolutely convergent
b. A number greater than 1, the series is divergent
c. A number equal to 1, the test is inconclusive

6. *Maclaurin's Integral Test.* Suppose $\sum a_n$ is a series of positive terms and f is a continuous decreasing function such that $f(x) \ge 0$ for $1 \le x < \infty$ and $f(n) = a_n$. Then the series and the improper integral $\int_1^\infty f(x)\,dx$ either both converge or both diverge.

SERIES SUMMATION AND IDENTITIES

Sums for the First *n* Numbers to Integer Powers

$$\sum_{j=1}^{n} j = \frac{n(n+1)}{2} = 1 + 2 + 3 + 4 + \cdots + n$$

$$\sum_{j=1}^{n} j^2 = \frac{n(n+1)(2n+1)}{6} = 1^2 + 2^2 + 3^2 + 4^2 + \cdots + n^2$$

$$\sum_{j=1}^{n} j^3 = \frac{n^2(n+1)^2}{4} = 1^3 + 2^3 + 3^3 + \cdots + n^3$$

$$\sum_{j=1}^{n} j^4 = \frac{n(n+1)(2n+1)(3n^2+3n-1)}{30} = 1^4 + 2^4 + 3^4 + \cdots + n^4$$

Arithmetic Progression

$$\sum_{k=1}^{n} [a + (k-1)d] = a + (a + d) + (a + 2d) + (a + 3d) + \cdots + [a + (n-1)]d$$

$$= na + \frac{1}{2}n(n-1)d$$

Geometric Progression

$$\sum_{j=1}^{n} ar^{j-1} = a + ar + ar^2 + ar^3 + \cdots + ar^{n-1}$$

$$= a\,\frac{1-r^n}{1-r} \qquad r \ne 1$$

Harmonic Progression

$$\sum_{k=0}^{n} \frac{1}{a+kd} = \frac{1}{a} + \frac{1}{a+d} + \frac{1}{a+2d} + \frac{1}{a+3d} + \frac{1}{a+4d} + \cdots + \frac{1}{a+nd}$$

The reciprocals of the terms of the arithmetic-progression series are called harmonic progression. No general summation formulas are available for this series.

Binomial Series

$$(x+y)^n = x^n + nx^{n-1}y + \frac{n(n-1)}{2!}x^{n-2}y^2 + \frac{n(n-1)(n-2)}{3!}x^{n-3}y^3 + \cdots + \frac{n!}{(n-r)!r!}x^{n-r}y^r + \cdots + y^n$$

$$(1 \pm x)^n = 1 \pm nx + \frac{n(n-1)}{2!}x^2 \pm \frac{n(n-1)(n-2)}{3!}x^3 + \cdots \quad (x^2 < 1)$$

Taylor's Series

$$f(x+h) = f(h) + xf'(h) + \frac{x^2}{2!}f''(h) + \frac{x^3}{3!}f'''(h) + \cdots$$

or $$f(x) = f(x_0) + f'(x_0)(x - x_0) + \frac{f''(x_0)}{2!}(x-x_0)^2 + \frac{f'''(x_0)}{3!}(x-x_0)^3 + \cdots$$

Example Find a series expansion for $f(x) = \ln(1 + x)$ about $x_0 = 0$.

$$f'(x) = (1+x)^{-1}, \quad f''(x) = -(1+x)^{-2}, \quad f'''(x) = 2(1+x)^{-3}, \text{ etc.}$$

thus $$f(0) = 0, \quad f'(0) = 1, \quad f''(0) = -1, \quad f'''(1) = 2, \text{ etc.}$$

$$\ln(x+1) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots + (-1)^{n+1}\frac{x^n}{n} + \cdots$$

which converges for $-1 < x \le 1$.

Maclaurin's Series

$$f(x) = f(0) + xf'(0) + \frac{x^2}{2!}f''(0) + \frac{x^3}{3!}f'''(0) + \cdots$$

This is simply a special case of Taylor's series when h is set to zero.

Exponential Series

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots + \frac{x^n}{n!} + \cdots \quad -\infty < x < \infty$$

Logarithmic Series

$$\ln x = \frac{x-1}{x} + \frac{1}{2}\left(\frac{x-1}{x}\right)^2 + \frac{1}{3}\left(\frac{x-1}{x}\right)^3 + \cdots \qquad (x > ½)$$

$$\ln x = 2\left[\left(\frac{x-1}{x+1}\right) + \frac{1}{3}\left(\frac{x-1}{x+1}\right)^3 + \cdots\right. \qquad (x > 0)$$

Trigonometric Series*

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots \qquad -\infty < x < \infty$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots \qquad -\infty < x < \infty$$

$$\sin^{-1} x = x + \frac{x^3}{6} + \frac{1}{2}\cdot\frac{3}{4}\cdot\frac{x^5}{5} + \frac{1}{2}\cdot\frac{3}{4}\cdot\frac{5}{6}\cdot\frac{x^7}{7} + \cdots \qquad (x^2 < 1)$$

$$\tan^{-1} x = x - \frac{1}{3}x^3 + \frac{1}{5}x^5 - \frac{1}{7}x^7 + \cdots \qquad (x^2 < 1)$$

Taylor Series The Taylor series for a function of two variables, expanded about the point (x_0, y_0), is

$$f(x, y) = f(x_0, y_0) + \left.\frac{\partial f}{\partial x}\right|_{x_0, y_0}(x - x_0) + \left.\frac{\partial f}{\partial y}\right|_{x_0, y_0}(y - y_0)$$

$$+ \frac{1}{2!}\left[\left.\frac{\partial^2 f}{\partial x^2}\right|_{x_0, y_0}(x-x_0)^2 + 2\left.\frac{\partial^2 f}{\partial x \partial y}\right|_{x_0, y_0}(x-x_0)(y-y_0) + \left.\frac{\partial^2 f}{\partial y^2}\right|_{x_0, y_0}(y-y_0)^2\right] + \cdots$$

Partial Sums of Infinite Series, and How They Grow Calculus textbooks devote much space to tests for convergence and divergence of series that are of little practical value, since a convergent

* tan x series has awkward coefficients and should be computed as $\left[(\text{sign})\dfrac{\sin x}{\sqrt{1-\sin^2 x}}\right]$.

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

series either converges rapidly, in which case almost any test (among those presented in the preceding subsections) will do; or it converges slowly, in which case it is not going to be of much use unless there is some way to get at its sum without adding up an unreasonable number of terms. To find out, as accurately as possible, how fast a convergent series converges and how fast a divergent series diverges, see Ref. 34.

COMPLEX VARIABLES

References: *General.* 73, 163, 172, 179. *Applied and computational complex analysis.* 141, 146, 179.

Numbers of the form $z = x + iy$, where x and y are real, $i^2 = -1$, are called complex numbers. The numbers $z = x + iy$ are representable in the plane as shown in Fig. 3-46. The following definitions and terminology are used:

1. Distance $OP = r$ = modulus of z written $|z|$. $|z| = \sqrt{x^2 + y^2}$.
2. x is the real part of z.
3. y is the imaginary part of z.
4. The angle θ, $0 \le \theta < 2\pi$, measured counterclockwise from the positive x axis to OP is the argument of z. $\theta = \arctan y/x = \arcsin y/r = \arccos x/r$ if $x \neq 0$, $\theta = \pi/2$ if $x = 0$ and $y > 0$.
5. The numbers r, θ are the polar coordinates of z.
6. $\bar{z} = x - iy$ is the complex conjugate of z.

ALGEBRA

Let $z_1 = x_1 + iy_1$, $z_2 = x_2 + iy_2$.

Equality $z_1 = z_2$ if and only if $x_1 = x_2$ and $y_1 = y_2$.

Addition $z_1 + z_2 = (x_1 + x_2) + i(y_1 + y_2)$.

Subtraction $z_1 - z_2 = (x_1 - x_2) + i(y_1 - y_2)$.

Multiplication $z_1 \cdot z_2 = (x_1x_2 - y_1y_2) + i(x_1y_2 + x_2y_1)$.

Division $z_1/z_2 = \dfrac{x_1x_2 + y_1y_2}{x_2^2 + y_2^2} + i\dfrac{x_2y_1 - x_1y_2}{x_2^2 + y_2^2}$, $z_2 \neq 0$.

SPECIAL OPERATIONS

$z\bar{z} = x^2 + y^2 = |z|^2$; $\overline{z_1 \pm z_2} = \bar{z}_1 \pm \bar{z}_2$; $\bar{\bar{z}}_1 = z_1$; $\overline{z_1z_2} = \bar{z}_1\bar{z}_2$; $|z_1 \cdot z_2| = |z_1| \cdot |z_2|$; $\arg(z_1 \cdot z_2) = \arg z_1 + \arg z_2$; $\arg(z_1/z_2) = \arg z_1 - \arg z_2$; $i^{4n} = 1$ for n any integer; $i^{2n} = -1$ where n is any odd integer; $z + \bar{z} = 2x$; $z - \bar{z} = 2iy$.

Every complex quantity can be expressed in the form $x + iy$.

TRIGONOMETRIC REPRESENTATION

By referring to Fig. 3-46, there results $x = r\cos\theta$, $y = r\sin\theta$ so that $z = x + iy = r(\cos\theta + i\sin\theta)$, which is called the polar form of the complex number. $\cos\theta + i\sin\theta = e^{i\theta}$. Hence $z = x + iy = re^{i\theta}$. $\bar{z} = x - iy = re^{-i\theta}$. Two important results from this are $\cos\theta = (e^{i\theta} + e^{-i\theta})/2$ and $\sin\theta = (e^{i\theta} - e^{-i\theta})/2i$. Let $z_1 = r_1e^{i\theta_1}$, $z_2 = r_2e^{i\theta_2}$. This form is convenient for multiplication for $z_1z_2 = r_1r_2e^{i(\theta_1+\theta_2)}$ and for division for $z_1/z_2 = (r_1/r_2)e^{i(\theta_1-\theta_2)}$, $z_2 \neq 0$.

POWERS AND ROOTS

If n is a positive integer, $z^n = (re^{i\theta})^n = r^ne^{in\theta} = r^n(\cos n\theta + i\sin n\theta)$.

If n is a positive integer,

$$z^{1/n} = r^{1/n}e^{i[(\theta+2k\pi)/n]} = r^{1/n}\left[\cos\left(\frac{\theta + 2k\pi}{n}\right) + i\sin\left(\frac{\theta + 2k\pi}{n}\right)\right]$$

and selecting values of $k = 0, 1, 2, 3, \ldots, n - 1$ give the n distinct values of $z^{1/n}$. The n roots of a complex quantity are uniformly spaced around a circle, with radius $r^{1/n}$, in the complex plane in a symmetric fashion.

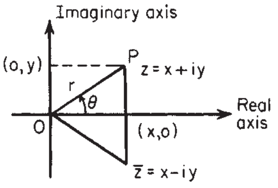

FIG. 3-46 Complex plane.

Example Find the three cube roots of −8. Here $r = 8$, $\theta = \pi$. The roots are $z_0 = 2(\cos\pi/3 + i\sin\pi/3) = 1 + i\sqrt{3}$, $z_1 = 2(\cos\pi + i\sin\pi) = -2$, $z_2 = 2(\cos 5\pi/3 + i\sin 5\pi/3) = 1 - i\sqrt{3}$.

ELEMENTARY COMPLEX FUNCTIONS

Polynomials A polynomial in z, $a_nz^n + a_{n-1}z^{n-1} + \cdots + a_0$, where n is a positive integer, is simply a sum of complex numbers times integral powers of z which have already been defined. Every polynomial of degree n has precisely n complex roots provided each multiple root of multiplicity m is counted m times.

Exponential Functions The exponential function e^z is defined by the equation $e^z = e^{x+iy} = e^x \cdot e^{iy} = e^z(\cos y + i\sin y)$. Properties: $e^0 = 1$; $e^{z_1} \cdot e^{z_2} = e^{z_1+z_2}$; $e^{z_1}/e^{z_2} = e^{z_1-z_2}$; $e^{z+2k\pi i} = e^z$.

Trigonometric Functions $\sin z = (e^{iz} - e^{-iz})/2i$; $\cos z = (e^{iz} + e^{-iz})/2$; $\tan z = \sin z/\cos z$; $\cot z = \cos z/\sin z$; $\sec z = 1/\cos z$; $\csc z = 1/\sin z$. Fundamental identities for these functions are the same as their real counterparts. Thus $\cos^2 z + \sin^2 z = 1$, $\cos(z_1 \pm z_2) = \cos z_1 \cos z_2 \mp \sin z_1 \sin z_2$, $\sin(z_1 \pm z_2) = \sin z_1 \cos z_2 \pm \cos z_1 \sin z_2$. The sine and cosine of z are periodic functions of period 2π; thus $\sin(z + 2\pi) = \sin z$. For computation purposes $\sin z = \sin(x + iy) = \sin x \cosh y + i\cos x \sinh y$, where $\sin x$, $\cosh y$, etc., are the real trigonometric and hyperbolic functions. Similarly, $\cos z = \cos x \cosh y - i\sin x \sinh y$. If $x = 0$ in the results given, $\cos iy = \cosh y$, $\sin iy = i\sinh y$.

Example Find all solutions of $\sin z = 3$. From previous data $\sin z = \sin x \cosh y + i\cos x \sinh y = 3$. Equating real and imaginary parts $\sin x \cosh y = 3$, $\cos x \sinh y = 0$. The second equation can hold for $y = 0$ or for $x = \pi/2, 3\pi/2, \ldots$. If $y = 0$, $\cosh 0 = 1$ and $\sin x = 3$ is impossible for real x. Therefore, $x = \pm\pi/2, \pm 3\pi/2, \ldots \pm(2n + 1)\pi/2$, $n = 0, \pm 1, \pm 2, \ldots$. However, $\sin 3\pi/2 = -1$ and $\cosh y \ge 1$. Hence $x = \pi/2, 5\pi/2, \ldots$. The solution is $z = [(4n + 1)\pi]/2 + i\cosh^{-1}3$, $n = 0, 1, 2, 3, \ldots$.

Example Find all solutions of $e^z = -i$. $e^z = e^x(\cos y + i\sin y) = -i$. Equating real and imaginary parts gives $e^x\cos y = 0$, $e^x\sin y = -1$. From the first $y = \pm\pi/2, \pm 3\pi/2, \ldots$. But $e^x > 0$. Therefore, $y = 3\pi/2, 7\pi/2, -\pi/2, \ldots$. Then $x = 0$. The solution is $z = i[(4n + 3)\pi]/2$.

Two important facets of these functions should be recognized. First, the $\sin z$ is *unbounded;* and, second, e^z takes *all* complex values *except* 0.

Hyperbolic Functions $\sinh z = (e^z - e^{-z})/2$; $\cosh z = (e^z + e^{-z})/2$; $\tanh z = \sinh z/\cosh z$; $\coth z = \cosh z/\sinh z$; $\operatorname{csch} z = 1/\sinh z$; $\operatorname{sech} z = 1/\cosh z$. Identities are: $\cosh^2 z - \sinh^2 z = 1$; $\sinh(z_1 + z_2) = \sinh z_1 \cosh z_2 + \cosh z_1 \sinh z_2$; $\cosh(z_1 + z_2) = \cosh z_1 \cosh z_2 + \sinh z_1 \sinh z_2$; $\cosh z + \sinh z = e^z$; $\cosh z - \sinh z = e^{-z}$. The hyperbolic sine and hyperbolic cosine are periodic functions with the imaginary period $2\pi i$. That is, $\sinh(z + 2\pi i) = \sinh z$.

Logarithms The logarithm of z, $\log z = \log|z| + i(\theta + 2n\pi)$, where $\log|z|$ is taken to the base e and θ is the principal argument of z, that is, the particular argument lying in the interval $0 \le \theta < 2\pi$. The logarithm of z is infinitely many valued. If $n = 0$, the resulting logarithm is called the principal value. The familiar laws $\log z_1z_2 = \log z_1 + \log z_2$, $\log z_1/z_2 = \log z_1 - \log z_2$, $\log z^n = n\log z$ hold for the principal value.

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Example $\log(1+i) = \log\sqrt{2} + i\left(\frac{\pi}{4} + 2n\pi\right)$.

General powers of z are defined by $z^\alpha = e^{\alpha \log z}$. Since $\log z$ is infinitely many valued, so too is z^α unless α is a rational number.

DeMoivre's formula can be derived from properties of e^z.

$$z^n = r^n(\cos\theta + i\sin\theta)^n = r^n(\cos n\theta + i\sin n\theta)$$

Thus $$(\cos\theta + i\sin\theta)^n = \cos n\theta + i\sin n\theta$$

Example $i^i = e^{i\log i} = e^{i[\log|i| + i(\pi/2 + 2n\pi)]} = e^{-(\pi/2+2n\pi)}$. Thus i^i is real with principal value $(n=0) = e^{-\pi/2}$.

Example $(\sqrt{2})^{1+i} = e^{(1+i)\log\sqrt{2}} = e^{\log\sqrt{2}}.\ e^{i\log\sqrt{2}} = \sqrt{2}.\ (\cos\log\sqrt{2} + i\sin\log\sqrt{2}) = \sqrt{2}[\cos(0.3466) + i\sin(0.3466)]$.

Inverse Trigonometric Functions $\cos^{-1} z = -i\log(z \pm \sqrt{z^2-1})$; $\sin^{-1} z = -i\log(iz \pm \sqrt{1-z^2})$; $\tan^{-1} z = \frac{i}{2}\log\left(\frac{i+z}{i-z}\right)$. These functions are infinitely many valued.

Inverse Hyperbolic Functions $\cosh^{-1} z = \log(z \pm \sqrt{z^2-1})$; $\sinh^{-1} z = \log(z \pm \sqrt{z^2+1})$; $\tanh^{-1} z = \frac{1}{2}\log\left(\frac{1+z}{1-z}\right)$.

COMPLEX FUNCTIONS (ANALYTIC)

In the real-number system a greater than $b(a > b)$ and b less than $c(b < c)$ define an order relation. These relations have no meaning for complex numbers. The absolute value is used for ordering. Some important relations follow: $|z| \geq x$; $|z| \geq y$; $|z_1 \pm z_2| \leq |z_1| + |z_2|$; $|z_1 - z_2| \geq ||z_1| - |z_2||$; $|z| \geq (|x| + |y|)/\sqrt{2}$. Parts of the complex plane, commonly called **regions** or **domains,** are described by using inequalities.

Example $|z-3| \leq 5$. This is equivalent to $\sqrt{(x-3)^2 + y^2} \leq 5$, which is the set of all points within and on the circle, centered at $x = 3$, $y = 0$ of radius 5.

Example $|z-1| \leq x$ represents the set of all points inside and on the parabola $2x = y^2 + 1$ or, equivalently, $2x \geq y^2 + 1$.

Functions of a Complex Variable If $z = x + iy$, $w = u + iv$ and if for each value of z in some region of the complex plane one or more values of w are defined, then w is said to be a function of z, $w = f(z)$. Some of these functions have already been discussed, e.g., $\sin z$, $\log z$. All functions are reducible to the form $w = u(x, y) + iv(x, y)$, where u, v are real functions of the real variables x and y.

Example $z^3 = (x+iy)^3 = x^3 + 3x^2(iy) + 3x(iy)^2 + (iy)^3 = (x^3 - 3xy^2) + i(3x^2y - y^3)$.

Example $\cos z = \cos x\cosh y - i\sin x\sinh y$.

Differentiation The *derivative* of $w = f(z)$ is

$$\frac{dw}{dz} = \lim_{\Delta z \to 0} \frac{f(z+\Delta z) - f(z)}{\Delta z}$$

and for the derivative to exist the limit must be the same no matter how Δz approaches zero. If w_1, w_2 are differentiable functions of z, the following rules apply:

$$\frac{d(w_1 \pm w_2)}{dz} = \frac{dw_1}{dz} \pm \frac{dw_2}{dz} \qquad \frac{d(w_1w_2)}{dz} = w_2\frac{dw_1}{dz} + w_1\frac{dw_2}{dz}$$

$$\frac{d(w_1/w_2)}{dz} = \frac{w_2(dw_1/dz) - w_1(dw_2/dz)}{w_2^2}$$

and $$\frac{dw_1^n}{dz} = nw_1^{n-1}\frac{dw_1}{dz}$$

For $w = f(z)$ to be differentiable, it is necessary that $\partial u/\partial x = \partial v/\partial y$ and $\partial v/\partial x = -\partial u/\partial y$. The last two equations are called the Cauchy-Riemann equations. The derivative

$$\frac{dw}{dz} = \frac{\partial u}{\partial x} + i\frac{\partial v}{\partial x} = \frac{\partial v}{\partial y} - i\frac{\partial u}{\partial y}$$

If $f(z)$ possesses a derivative at z_o and at every point in some neighborhood of z_0, then $f(z)$ is said to be analytic at z_0. If the Cauchy-Riemann equations are satisfied and

$$u,\ v,\ \frac{\partial u}{\partial x}, \frac{\partial u}{\partial y}, \frac{\partial v}{\partial x}, \frac{\partial v}{\partial y}$$

are continuous in a region of the complex plane, then $f(z)$ is analytic in that region.

Example $w = z\bar{z} = x^2 + y^2$. Here $u = x^2 + y^2$, $v = 0$. $\partial u/\partial x = 2x$, $\partial u/\partial y = 2y$, $\partial v/\partial x = \partial v/\partial y = 0$. These are continuous everywhere, but the Cauchy-Riemann equations hold only at the origin. Therefore, w is nowhere analytic, but it is differentiable at $z = 0$ only.

Example $w = e^z = e^x\cos y + ie^x\sin y$. $u = e^x\cos y$, $v = e^x\sin y$. $\partial u/\partial x = e^x\cos y$, $\partial u/\partial y = -e^x\sin y$, $\partial v/\partial x = e^x\sin y$, $\partial v/\partial y = e^x\cos y$. The continuity and Cauchy-Riemann requirements are satisfied for all finite z. Hence e^z is analytic (except at ∞) and $dw/dz = \partial u/\partial x + i(\partial v/\partial x) = e^z$.

Example $w = \frac{1}{z} = \frac{x - iy}{x^2+y^2} = \frac{x}{x^2+y^2} - i\frac{y}{x^2+y^2}$

It is easy to see that dw/dz exists except at $z = 0$. Thus $1/z$ is analytic except at $z = 0$.

Singular Points If $f(z)$ is analytic in a region except at certain points, those points are called singular points.

Example $1/z$ has a singular point at zero.

Example $\tan z$ has singular points at $z = \pm(2n+1)(\pi/2)$, $n = 0, 1, 2, \ldots$.

The derivatives of the common functions, given earlier, are the same as their real counterparts.

Example $(d/dz)(\log z) = 1/z$, $(d/dz)(\sin z) = \cos z$.

Harmonic Functions Both the *real* and the *imaginary* parts of any analytic function $f = u + iv$ satisfy Laplace's equation $\partial^2\phi/\partial x^2 + \partial^2\phi/\partial y^2 = 0$. A function which possesses continuous second partial derivatives and satisfies Laplace's equation is called a harmonic function.

Example $e^z = e^x\cos y + ie^x\sin y$. $u = e^x\cos y$, $\partial u/\partial x = e^x\cos y$, $\partial^2u/\partial x^2 = e^x\cos y$, $\partial u/\partial y = -e^x\sin y$, $\partial^2u/\partial y^2 = -e^x\cos y$. Clearly $\partial^2u/\partial x^2 + \partial^2u/\partial y^2 = 0$. Similarly, $v = e^x\sin y$ is also harmonic.

If $w = u + iv$ is analytic, the curves $u(x, y) = c$ and $v(x, y) = k$ intersect at right angles, if $w^i(z) \neq 0$.

Example $z^3 = (x^3 - 3xy^2) + i(3x^2y - y^3)$. Set $u = x^3 - 3xy^2 = c$, $v = 3x^2y - y^3 = k$. By implicit differentiation there results, respectively, $dy/dx = (x^2 - y^2)/2xy$, $dy/dx = 2xy/(y^2 - x^2)$, which are clearly negative reciprocals, the condition for perpendicularity.

Integration In much of the work with complex variables a simple extension of integration called line or curvilinear integration is of fundamental importance. Since any complex line integral can be expressed in terms of real line integrals, we define only real line integrals. Let $F(x,y)$ be a real, continuous function of x and y and c be any continuous curve of finite length joining the points A and B (Fig. 3-47). $F(x,y)$ is not related to the curve c. Divide c up into n segments, Δs_i, whose projection on the x axis is Δx_i and on the y axis is Δy_i. Let (ε_i, η_i) be the coordinates of an arbitrary point on Δs_i. The limits of the sums

$$\lim_{\Delta s_i \to 0} \sum_{i=1}^{n} F(\varepsilon_i, \eta_i)\,\Delta s_i = \int_c F(x, y)\,ds$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

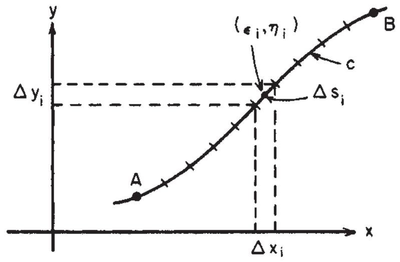

FIG. 3-47 Line integral.

$$\lim_{\Delta s_i \to 0} \sum_{i=1}^{n} F(\varepsilon_i, \eta_i)\, \Delta x_i = \int_c F(x, y)\, dx$$

$$\lim_{\Delta s_i \to 0} \sum_{i=1}^{n} F(\varepsilon_i, \eta_i)\, \Delta y_i = \int_c F(x, y)\, dy$$

are known as line integrals. Much of the initial strangeness of these integrals will vanish if it be observed that the ordinary definite integral $\int_a^b f(x)\, dx$ is just a line integral in which the curve c is a line segment on the x axis and $F(x, y)$ is a function of x alone. The evaluation of line integrals can be reduced to evaluation of ordinary integrals.

Example $\int_c y(1 + x)\, dy$, where c: $y = 1 - x^2$ from $(-1, 0)$ to $(1, 0)$. Clearly $y = 1 - x^2$, $dy = -2x\, dx$. Thus $\int_c y(1 + x)\, dy = -2 \int_{-1}^{1} (1 - x^2)(1 + x)x\, dx = -8/15$.

Example $\int_c x^2 y\, ds$, c is the square whose vertices are (0, 0), (1, 0), (1, 1), (0, 1). $ds = \sqrt{dx^2 + dy^2}$. When $dx = 0$, $ds = dy$. From (0, 0) to (1, 0), $y = 0$, $dy = 0$. Similar arguments for the other sides give

$$\int_c x^2 y\, ds = \int_0^1 0.x^2\, dx + \int_0^1 y\, dy + \int_1^0 x^2\, dx + \int_1^0 0.y\, dy = 1/2 - 1/3 = 1/6$$

Let $f(z)$ be any function of z, analytic or not, and c any curve as above. The complex integral is calculated as $\int_c f(z)\, dz = \int_c (u\, dx - v\, dy) + i \int_c (v\, dx + u\, dy)$, where $f(z) = u(x, y) + iv(x, y)$. Properties of line integrals are the same as those for ordinary integrals. That is, $\int_c [f(z) \pm g(z)]\, dz = \int_c f(z)\, dz \pm \int_c g(z)\, dz$; $\int_c kf(z)\, dz = k \int_c f(z)\, dz$ for any constant k, etc.

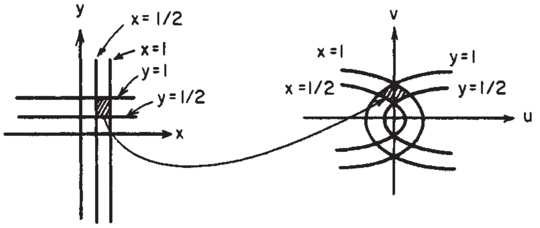

FIG. 3-48 Conformal transformation.

Example $\int_c (x^2 + iy)\, dz$ along c: $y = x$, 0 to $1 + i$. This becomes

$$\int_c (x^2 + iy)\, dz = \int_c (x^2\, dx - y\, dy)$$

$$+ i \int_c (y\, dx + x^2\, dy) = \int_0^1 x^2\, dx - \int_0^1 x\, dx + i \int_0^1 x\, dx + i \int_0^1 x^2\, dx = -1/6 + 5i/6$$

Conformal Mapping Every function of a complex variable $w = f(z) = u(x, y) + iv(x, y)$ transforms the x, y plane into the u, v plane in some manner. A conformal transformation is one in which angles between curves are preserved in *magnitude* and *sense.* Every analytic function, except at those points where $f'(z) = 0$, is a conformal transformation. See Fig. 3-48.

Example $w = z^2$. $u + iv = (x^2 - y^2) + 2ixy$ or $u = x^2 - y^2$, $v = 2xy$. These are the transformation equations between the (x, y) and (u, v) planes. Lines parallel to the x axis, $y = c_1$ map into curves in the u, v plane with parametric equations $u = x^2 - c_1^2$, $v = 2c_1 x$. Eliminating x, $u = (v^2/4c_1^2) - c_1^2$, which represents a family of parabolas with the origin of the w plane as focus, the line $v = 0$ as axis and opening to the right. Similar arguments apply to $x = c_2$.

The principles of complex variables are useful in the solution of a variety of applied problems. See the references for additional information.

The natural laws in any scientific or technological field are not regarded as precise and definitive until they have been expressed in mathematical form. Such a form, often an equation, is a relation between the quantity of interest, say, product yield, and independent variables such as time and temperature upon which yield depends. When it happens that this equation involves, besides the function itself, one or more of its derivatives it is called a differential equation.

Example The homogeneous bimolecular reaction $A + B \xrightarrow{k} C$ is characterized by the differential equation $dx/dt = k(a - x)(b - x)$, where a = initial concentration of A, b = initial concentration of B, and $x = x(t)$ = concentration of C as a function of time t.

Example The differential equation of heat conduction in a moving fluid with velocity components v_x, v_y is

$$\frac{\partial u}{\partial t} + v_x \frac{\partial u}{\partial x} + v_y \frac{\partial u}{\partial y} = \frac{K}{\rho c_p} \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right)$$

where $u = u(x, y, t)$ = temperature, K = thermal conductivity, ρ = density, and c_p = specific heat at constant pressure.

ORDINARY DIFFERENTIAL EQUATIONS

When the function involved in the equation depends upon only one variable, its derivatives are ordinary derivatives and the differential equation is called an ordinary differential equation. When the function depends upon several independent variables, then the equation is called a partial differential equation. The theories of ordinary and partial differential equations are quite different. In almost every respect the latter is more difficult.

Whichever the type, a differential equation is said to be of nth order if it involves derivatives of order n but no higher. The equation in the first example is of first order and that in the second example of second order. The degree of a differential equation is the power to which the derivative of the highest order is raised after the equation has been cleared of fractions and radicals in the dependent variable and its derivatives.

A relation between the variables, involving no derivatives, is called a solution of the differential equation if this relation, when substituted in the equation, satisfies the equation. A solution of an ordinary differential equation which includes the maximum possible number of "arbitrary" constants is called the **general solution.** The maximum number of "arbitrary" constants is exactly equal to the order of the dif-

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

ferential equation. If any set of specific values of the constants is chosen, the result is called a **particular solution.**

Example The general solution of $(d^2x/dt^2) + k^2x = 0$ is $x = A \cos kt + B \sin kt$, where A, B are arbitrary constants. A particular solution is $x = \frac{1}{2} \cos kt + 3 \sin kt$.

In the case of some equations still other solutions exist called singular solutions. A **singular solution** *is any solution of the differential equation which is not included in the general solution.*

Example $y = x(dy/dx) - \frac{1}{4}(dy/dx)^2$ has the general solution $y = cx - \frac{1}{4}c^2$, where c is an arbitrary constant; $y = x^2$ is a singular solution, as is easily verified.

ORDINARY DIFFERENTIAL EQUATIONS OF THE FIRST ORDER

Equations with Separable Variables Every differential equation of the first order and of the first degree can be written in the form $M(x, y)\, dx + N(x, y)\, dy = 0$. If the equation can be transformed so that M does not involve y and N does not involve x, then the variables are said to be separated. The solution can then be obtained by **quadrature,** which means that $y = \int f(x)\, dx + c$, which may or may not be expressible in simpler form.

Example Two liquids A and B are boiling together in a vessel. Experimentally it is found that the ratio of the rates at which A and B are evaporating at any time is proportional to the ratio of the amount of A (say, x) to the amount of B (say, y) still in the liquid state. This physical law is expressible as $(dy/dt)/(dx/dt) = ky/x$ or $dy/dx = ky/x$, where k is a proportionality constant. This equation may be written $dy/y = k(dx/x)$, in which the variables are separated. The solution is $\ln y = k \ln x + \ln c$ or $y = cx^k$.

Exact Equations The equation $M(x, y)\, dx + N(x, y)\, dy = 0$ is exact if and only if $\partial M/\partial y = \partial N/\partial x$. In this case there exists a function $w = f(x, y)$ such that $\partial f/\partial x = M$, $\partial f/\partial y = N$, and $f(x, y) = C$ is the required solution. $f(x, y)$ is found as follows: treat y as though it were constant and evaluate $\int M(x, y)\, dx$. Then treat x as though it were constant and evaluate $\int N(x, y)\, dy$. The sum of all unlike terms in these two integrals (including no repetitions) is $f(x, y)$.

Example $(2xy - \cos x)\, dx + (x^2 - 1)\, dy = 0$ is exact for $\partial M/\partial y = 2x$, $\partial N/\partial x = 2x$. $\int M\, dx = \int (2xy - \cos x)\, dx = x^2y - \sin x$, $\int N\, dy = \int (x^2 - 1)\, dy = x^2y - y$. The solution is $x^2y - \sin x - y = C$, as may easily be verified.

Linear Equations A differential equation is said to be linear when it is of first degree in the dependent variable and its derivatives. The general linear first-order differential equation has the form $dy/dx + P(x)y = Q(x)$. Its general solution is

$$y = e^{-\int P\, dx} \left[\int Q e^{\int P\, dx}\, dx + C \right]$$

Example A tank initially holds 200 gal of a salt solution in which 100 lb is dissolved. Six gallons of brine containing 4 lb of salt run into the tank per minute. If mixing is perfect and the output rate is 4 gal/min, what is the amount A of salt in the tank at time t? The differential equation of A is $dA/dt + [1/(100 + t)]A = 4$. Its general solution is $A = 2(100 + t) + C/(100 + t)$. At $t = 0$, ′$A = 100$; so the particular solution is $A = 2(100 + t) - 10^4/(100 + t)$.

ORDINARY DIFFERENTIAL EQUATIONS OF HIGHER ORDER

The higher-order differential equations, especially those of order 2, are of great importance because of physical situations describable by them.

Equation $y^{(n)} = f(x)$ Such a differential equation can be solved by n integrations. The solution will contain n arbitrary constants.

Linear Differential Equations with Constant Coefficients and Right-Hand Member Zero (Homogeneous) The solution of $y'' + ay' + by = 0$ depends upon the nature of the roots of the characteristic equation $m^2 + am + b = 0$ obtained by substituting the trial solution $y = e^{mx}$ in the equation.

Distinct Real Roots If the roots of the characteristic equation are distinct real roots, r_1 and r_2, say, the solution is $y = Ae^{r_1x} + Be^{r_2x}$, where A and B are arbitrary constants.

Example $y'' + 4y' + 3 = 0$. The characteristic equation is $m^2 + 4m + 3 = 0$. The roots are -3 and -1, and the general solution is $y = Ae^{-3x} + Be^{-x}$.

Multiple Real Roots If $r_1 = r_2$, the solution of the differential equation is $y = e^{r_1x}(A + Bx)$.

Example $y'' + 4y + 4 = 0$. The characteristic equation is $m^2 + 4m + 4 = 0$ with roots -2 and -2. The solution is $y = e^{-2x}(A + Bx)$.

Complex Roots If the characteristic roots are $p \pm iq$, then the solution is $y = e^{px}(A \cos qx + B \sin qx)$.

Example The differential equation $My'' + Ay' + ky = 0$ represents the vibration of a linear system of mass M, spring constant k, and damping constant A. If $A < 2\sqrt{kM}$, the roots of the characteristic equation

$$Mm^2 + Am + k = 0 \text{ are complex } -\frac{A}{2M} \pm i\sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2}$$

and the solution is $y = e^{-(At/2M)}$

$$\left\{c_1 \cos\left(\sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2}\right) t + c_2 \sin\left(\sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2}\right) t\right\}$$

This solution is oscillatory, representing undercritical damping.

All these results generalize to homogeneous linear differential equations with constant coefficients of order higher than 2. These equations (especially of order 2) have been much used because of the ease of solution. Oscillations, electric circuits, diffusion processes, and heat-flow problems are a few examples for which such equations are useful.

Second-Order Equations: Dependent Variable Missing Such an equation is of the form

$$F\left(x, \frac{dy}{dx}, \frac{d^2y}{dx^2}\right) = 0$$

It can be reduced to a first-order equation by substituting $p = dy/dx$ and $dp/dx = d^2y/dx^2$.

Second-Order Equations: Independent Variable Missing Such an equation is of the form

$$F\left(y, \frac{dy}{dx}, \frac{d^2y}{dx^2}\right) = 0$$

Set
$$\frac{dy}{dx} = p, \quad \frac{d^2y}{dx^2} = p\frac{dp}{dy}$$

The result is a first-order equation in p,

$$F\left(y, p, p\frac{dp}{dy}\right) = 0$$

Example The capillary curve for one vertical plate is given by

$$\frac{d^2y}{dx^2} = \frac{4y}{c^2}\left[1 + \left(\frac{dy}{dx}\right)^2\right]^{3/2}$$

Its solution by this technique is

$$x + \sqrt{c^2 - y^2} - \sqrt{c^2 - h_0^2} = \frac{c}{2}\left(\cosh^{-1}\frac{c}{y} - \cosh^{-1}\frac{c}{h_0}\right)$$

where c, h_0 are physical constants.

Example The equation governing chemical reaction in a porous catalyst in plane geometry of thickness L is

$$D\frac{d^2c}{dx^2} = k f(c), \quad \frac{dc}{dx}(0) = 0, \quad c(L) = c_0$$

where D is a diffusion coefficient, k is a reaction rate parameter, c is the concentration, $k f(c)$ is the rate of reaction, and c_0 is the concentration at the boundary. Making the substitution gives

$$p\frac{dp}{dc} = \frac{k}{D} f(c)$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

Integrating gives $$\frac{p^2}{2} = \frac{k}{D}\int_{c(0)}^{c} f(c)\,dc$$

If the reaction is very fast, $c(0) \approx 0$ and the average reaction rate is related to $p(L)$. See Ref. 106. This variable is given by

$$p(L) = \left[\frac{2k}{D}\int_0^{c0} f(c)\,dc\right]^{1/2}$$

Thus, the average reaction rate can be calculated without solving the complete problem.

Linear Nonhomogeneous Differential Equations

***Linear Differential Equations Right-Hand Member* f(x) ≠ 0** Again the specific remarks for $y'' + ay' + by = f(x)$ apply to differential equations of similar type but higher order. We shall discuss two general methods.

Method of Undetermined Coefficients Use of this method is limited to equations exhibiting both constant coefficients and particular forms of the function $f(x)$. In most cases $f(x)$ will be a sum or product of functions of the type constant, x^n (n a positive integer), e^{mx}, $\cos kx$, $\sin kx$. When this is the case, the solution of the equation is $y = H(x) + P(x)$, where $H(x)$ is a solution of the homogeneous equations found by the method of the preceding subsection and $P(x)$ is a particular integral found by using the following table subject to these conditions: (1) When $f(x)$ consists of the sum of several terms, the appropriate form of $P(x)$ is the sum of the particular integrals corresponding to these terms individually. (2) When a term in any of the trial integrals listed is already a part of the homogeneous solution, the indicated form of the particular integral is multiplied by x.

Form of Particular Integral

If $f(x)$ is	Then $P(x)$ is
a (constant)	A (constant)
ax^n	$A_nx^n + A_{n-1}x^{n-1} + \cdots A_1x + A_0$
ae^{rx}	Be^{rx}
$c\cos kx$ $d\sin kx$	$A\cos kx + B\sin kx$
$gx^ne^{rx}\cos kx$ $hx^ne^{rx}\sin kx$	$(A_nx^n + \cdots + A_0)e^{rx}\cos kx + (B_nx^n + \cdots + B_0)e^{rx}\sin kx$

Since the form of the particular integral is known, the constants may be evaluated by substitution in the differential equation.

Example $y'' + 2y' + y = 3e^{2x} - \cos x + x^3$. The characteristic equation is $(m+1)^2 = 0$ so that the homogeneous solution is $y = (c_1 + c_2x)e^{-x}$. To find a particular solution we use the trial solution from the table, $y = a_1e^{2x} + a_2\cos x + a_3\sin x + a_4x^3 + a_5x^2 + a_6x + a_7$. Substituting this in the differential equation collecting and equating like terms, there results $a_1 = 1/3$, $a_2 = 0$, $a_3 = -1/2$, $a_4 = 1$, $a_5 = -6$, $a_6 = 18$, and $a_7 = -24$. The solution is $y = (c_1 + c_2x)e^{-x} + \frac{1}{3}e^{2x} - \frac{1}{2}\sin x + x^3 - 6x^2 + 18x - 24$.

Method of Variation of Parameters This method is applicable to any linear equation. The technique is developed for a second-order equation but immediately extends to higher order. Let the equation be $y'' + a(x)y' + b(x)y = R(x)$ and let the solution of the homogeneous equation, found by some method, be $y = c_1f_1(x) + c_2f_2(x)$. It is now assumed that a particular integral of the differential equation is of the form $P(x) = uf_1 + vf_2$ where u, v are functions of x to be determined by two equations. One equation results from the requirement that $uf_1 + vf_2$ satisfy the differential equation, and the other is a degree of freedom open to the analyst. The best choice proves to be

$$u'f_1 + v'f_2 = 0 \qquad \text{and} \qquad u'f_1' + v'f_2' = R(x)$$

Then $$u' = \frac{du}{dx} = -\frac{f_2}{f_1f_2' - f_2f_1'}R(x)$$

$$v' = \frac{dv}{dx} = \frac{f_1}{f_1f_2' - f_2f_1'}R(x)$$

and since f_1, f_2, and R are known u, v may be found by direct integration.

Example $(1-x^2)\dfrac{d^2y}{dx^2} - \dfrac{1}{x}\dfrac{dy}{dx} = x$. The homogeneous equation

$$(1-x^2)\frac{d^2y}{dx^2} - \frac{1}{x}\frac{dy}{dx} = 0$$

reduces to $$\frac{dp}{p} = \frac{dx}{x(1-x^2)}$$

when we set $dy/dx = p$. Upon integrating twice, $y = c_1\sqrt{x^2-1} + c_2$ is the homogeneous solution. Now assume that the particular solution has the form $y = u\sqrt{x^2-1} + v$. The equations for u and v become

$$u' = du/dx = \sqrt{x^2-1}$$

$$v' = \frac{dv}{dx} = 1 - x^2$$

so that

$$u = \frac{1}{2}[x\sqrt{x^2-1} - \ln(x + \sqrt{x^2-1})] \qquad \text{and} \qquad v = x - x^3/3.$$

The complete solution is

$$y = c_1\sqrt{x^2-1} + c_2 + \frac{x}{2} - \frac{x^3}{6} - \frac{1}{2}\sqrt{x^2-1}\ln(x + \sqrt{x^2-1}).$$

Perturbation Methods If the ordinary differential equation has a parameter that is small and is not multiplying the highest derivative, perturbation methods can give solutions for small values of the parameter.

Example Consider the differential equation for reaction and diffusion in a catalyst; the reaction is second order: $c'' = ac^2$, $c'(0) = 0$, $c(1) = 1$. The solution is expanded in the following Taylor series in a.

$$c(x, a) = c_0(x) + ac_1(x) + a^2c_2(x) + \cdots$$

The goal is to find equations governing the functions $\{c_i(x)\}$ and solve them. Substitution into the equations gives the following equations:

$$c_0''(x) + a\,c_1''(x) + a^2c_2''(x) + \cdots = a[c_0(x) + ac_1(x) + a^2c_2(x) + \cdots]^2$$

$$c_0'(0) + ac_1'(0) + a^2c_2'(0) + \cdots = 0$$

$$c_0(1) + ac_1(1) + a^2c_2(1) + \cdots = 1$$

Like terms in powers of a are collected to form the individual problems.

$$c_0'' = 0, \quad c_0'(0) = 0, \quad c_0(1) = 1$$

$$c_1'' = c_0^2, \quad c_1'(0) = 0, \quad c_1(1) = 0$$

$$c_2'' = 2c_0c_1, \quad c_2'(0) = 0, \quad c_2(1) = 0$$

The solution proceeds in turn.

$$c_0(x) = 1, \quad c_1(x) = \frac{(x^2-1)}{2}, \quad c_2(x) = \frac{5 - 6x^2 + x^4}{12}$$

SPECIAL DIFFERENTIAL EQUATIONS (SEE REF. 1)

Euler's Equation The linear equation $x^ny^{(n)} + a_1x^{n-1}y^{(n-1)} + \cdots + a_{n-1}xy' + a_ny = R(x)$ can be reduced to a linear equation with constant coefficients by the change of variable $x = e^t$. To solve the homogeneous equation substitute $y = x^r$ into it, cancel the powers of x, which are the same for all terms, and solve the resulting polynomial for r. In case of multiple or complex roots there results the form $y = x^r(\log x)^r$ and $y = x^\alpha[\cos(\beta\log x) + i\sin(\beta\log x)]$.

Example Solve $x^2y'' - 2y = 0$. By setting $y = x^r$, $x^r[r(r-1) - 2] = 0$. The roots of $r^2 - r - 2 = 0$ are $r = 2, -1$. The general solution is $y = Ax^2 + B/x$.

The equation $(ax+b)^ny^{(n)} + a_1(ax+b)^{n-1}y^{(n-1)} + \cdots + a_ny = R(x)$ can be reduced to the Euler form by the substitution $ax + b = z$. It may be treated without change of variable, the homogeneous equation having solutions of the form $y = (ax+b)^r$.

Bessel's Equation The linear equation $x^2(d^2y/dx^2) + (1-2\alpha)x(dy/dx) + [\beta^2\gamma^2x^{2\gamma} + (\alpha^2 - p^2\gamma^2)]y = 0$ is the general Bessel equation. By series methods, not to be discussed here, this equation can be shown to have the solution

$$y = Ax^\alpha J_p(\beta x^\gamma) + Bx^\alpha J_{-p}(\beta x^\gamma) \qquad p \text{ not an integer or zero}$$

$$y = Ax^\alpha J_p(\beta x^\gamma) + Bx^\alpha Y_p(\beta x^\gamma) \qquad p \text{ an integer}$$

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

where $$J_p(x) = \left(\frac{x}{2}\right)^p \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{2k}}{k!\Gamma(p+k+1)}$$

$$J_{-p}(x) = \left(\frac{x}{2}\right)^{-p} \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{2k}}{k!\Gamma(k+1-p)} \qquad p \text{ not an integer}$$

$$\Gamma(n) = \int_0^{\infty} x^{n-1} e^{-x}\, dx \qquad n > 0$$

is the gamma function. For p an integer

$$J_p(x) = \left(\frac{x}{2}\right)^p \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{2k}}{k!(p+k)!}$$

(Bessel function of the first kind of order p)

$$Y_p(x) = \frac{[J_p(x)\cos(p\pi) - J_{-p}(x)]}{\sin(p\pi)}$$

(replace right-hand side by limiting value if P is an integer or zero).

The series converge for all x. Much of the importance of Bessel's equation and Bessel functions lies in the fact that the solutions of numerous linear differential equations can be expressed in terms of them.

Example $d^2y/dx^2 + [9x - (63/4x^2)]y = 0$. In general form this is $x^2(d^2y/dx^2) + (9x^3 - 63/4)y = 0$. Thus $\alpha = 1/2$, $\gamma = 3/2$; $\beta = 2$, $p = 5/3$. The solution is (since $p \neq$ integer) $y = Ax^{1/2}J_{5/3}(2x^{3/2}) + Bx^{1/2}J_{-5/3}(2x^{3/2})$. Tables are available for the evaluation of many of these functions.

Example The heat flow through a wedge-shaped fin is characterized by the equation $x^2(d^2y/dx^2) + x(dy/dx) - a^2xy = 0$, where $y = T - T_{air}$, α is a combination of physical constants, and x = distance from fin end. By comparing this with the standard equation, there results $\alpha = 0$, $p = 0$, $\gamma = 1/2$, $\beta^2 = -4a^2$ or $\beta = 2ai$. The solution is $y = AJ_0(2ai\sqrt{x}) + BY_0(2ai\sqrt{x})$.

Legendre's Equation The Legendre equation $(1 - x^2)y'' - 2xy' + n(n+1)y = 0$, $n \geq 0$, has the solution $y = Au_n(x) + Bv_n(x)$ for n not an integer where

$$u_n(x) = 1 - \frac{n(n+1)}{2!}x^2 + \frac{n(n-2)(n+1)(n+3)}{4!}x^4 - \frac{n(n-2)(n-4)(n+1)(n+3)(n+5)}{6!}x^6 + \cdots$$

$$v_n(x) = x - \frac{(n-1)(n+2)}{3!}x^3 + \frac{(n-1)(n-3)(n+2)(n+4)}{5!}x^5 - \cdots.$$

If n is an even integer or zero, u_n is a polynomial in x. If n is an odd integer, then v_n is a polynomial. The interval of convergence for the series is $-1 < x < 1$. If n is an integer, set

$$P_n(x) = \frac{u_n(x)}{u_n(1)} \ (n \text{ even or zero}), \qquad P_n = \frac{v_n(x)}{v_n(1)} \ (n \text{ odd})$$

The polynomials P_n are the so-called Legendre polynomials, $P_0(x) = 1$, $P_1(x) = x$, $P_2(x) = 1/2(3x^2 - 1)$, $P_3(x) = 1/2(5x^3 - 3x)$, ...

Laguerre's Equation The Laguerre equation $x(d^2y/dx^2) + (c - x)(dy/dx) - ay = 0$ is satisfied by the confluent hypergeometric function. See Refs. 1 and 173.

Hermite's Equation The Hermite equation $y'' - 2xy' + 2ny = 0$ is satisfied by the Hermite polynomial of degree n, $y = AH_n(x)$ if n is a positive integer or zero. $H_0(x) = 1$, $H_1(x) = 2x$, $H_2(x) = 4x^2 - 2$, $H_3(x) = 8x^3 - 12x$, $H_4(x) = 16x^4 - 48x^2 + 12$, $H_{r+1}(x) = 2xH_r(x) - 2rH_{r-1}(x)$.

Example $y'' - 2xy' + 6y = 0$. Here $n = 3$; so $y = AH_3 = A(8x^3 - 12x)$ is a solution.

Chebyshev's Equation The equation $(1 - x^2)y'' - xy' + n^2y = 0$ for n a positive integer or zero is satisfied by the nth Chebyshev polynomial $y = AT_n(x)$. $T_0(x) = 1$, $T_1(x) = x$, $T_2(x) = 2x^2 - 1$, $T_3(x) = 4x^3 - 3x$, $T_4(x) = 8x^4 - 8x^2 + 1$; $T_{r+1}(x) = 2xT_r(x) - T_{r-1}(x)$.

Example $(1 - x^2)y'' - xy' + 36y = 0$. Here $n = 6$. A solution is $y = T_6(x) = 2xT_5(x) - T_4(x) = 2x(2xT_4 - T_3) - T_4 = 32x^6 - 48x^4 + 18x^2 - 1$. Further details on these special equations and others can be found in the literature.

PARTIAL DIFFERENTIAL EQUATIONS

The analysis of situations involving two or more independent variables frequently results in a partial differential equation.

Example The equation $\partial T/\partial t = K(\partial^2 T/\partial x^2)$ represents the unsteady one-dimensional conduction of heat.

Example The equation for the unsteady transverse motion of a uniform beam clamped at the ends is

$$\frac{\partial^4 y}{\partial x^4} + \frac{\rho}{EI}\frac{\partial^2 y}{\partial t^2} = 0$$

Example The expansion of a gas behind a piston is characterized by the simultaneous equations

$$\frac{\partial u}{\partial t} + u\frac{\partial u}{\partial x} + \frac{c^2}{\rho}\frac{\partial \rho}{\partial x} = 0 \quad \text{and} \quad \frac{\partial \rho}{\partial t} + u\frac{\partial \rho}{\partial x} + \rho\frac{\partial u}{\partial x} = 0$$

Example The heating of a diathermanous solid is characterized by the equation $\alpha(\partial^2\theta/\partial x^2) + \beta e^{-\gamma x} = \partial\theta/\partial t$.

The partial differential equation $\partial^2 f/\partial x\, \partial y = 0$ can be solved by two integrations yielding the solution $f = g(x) + h(y)$, where $g(x)$ and $h(y)$ are arbitrary differentiable functions. This result is an example of the fact that the general solution of partial differential equations involves arbitrary functions in contrast to the solution of ordinary differential equations, which involve only arbitrary constants. A number of methods are available for finding the general solution of a partial differential equation. In most applications of partial differential equations the general solution is of limited use. In such applications the solution of a partial differential equation must satisfy both the equation and certain auxiliary conditions called **initial** and/or **boundary** conditions, which are dictated by the problem. Examples of these include those in which the wall temperature is a fixed constant $T(x_0) = T_0$, there is no diffusion across a nonpermeable wall, and the like. In ordinary differential equations these auxiliary conditions allow definite numbers to be assigned to the constants of integration. In partial differential equations the boundary conditions demand that the arbitrary functions resulting from integration assume specific forms. Except for a few cases (some first-order equations, D'Alembert's solution of the wave equation, and others) a procedure which first determines the arbitrary functions and then specializes them to fit the boundary conditions is usually not feasible. A more fruitful attack is to determine directly a set of particular solutions and then combine them so that the boundary conditions are satisfied. The only area in which much analysis has been accomplished is for linear homogeneous partial differential equations. Such equations have the property that if $f_1, f_2, \ldots, f_n, \ldots$ are individually solutions, then the function $f = \sum_{i=1}^{\infty} f_i$ is also a solution, provided the series converges and is differentiable up to the order (termwise) of the equation.

Partial Differential Equations of Second and Higher Order Many of the applications to scientific problems fall naturally into partial differential equations of second order, although there are important exceptions in elasticity, vibration theory, and elsewhere.

A second-order differential equation can be written as

$$a\frac{\partial^2 u}{\partial x^2} + b\frac{\partial^2 u}{\partial x \partial y} + c\frac{\partial^2 u}{\partial y^2} = f$$

where a, b, c, and f depend upon x, y, u, $\partial u/\partial x$, and $\partial u/\partial y$. This equation is hyperbolic, parabolic, or elliptic, depending on whether the discriminant $b^2 - 4ac$ is >0, =0, or <0, respectively. Since a, b, c, and f depend on the solution, the type of equation can be different at different x and y locations. If the equation is hyperbolic, discontinuities can be propagated. See Refs. 11, 79, 105, 159, and 192.

Phenomena of **propagation** such as vibrations are characterized by equations of "hyperbolic" type which are essentially different in their properties from other classes such as those which describe equilibrium (elliptic) or unsteady diffusion and heat transfer (parabolic). Prototypes are as follows:

Elliptic Laplace's equation $\partial^2u/\partial x^2 + \partial^2u/\partial y^2 = 0$ and Poisson's equation $\partial^2u/\partial x^2 + \partial^2u/\partial y^2 = g(x, y)$ do not contain the variable time

explicitly and consequently represent equilibrium configurations. Laplace's equation is satisfied by static electric or magnetic potential at points free from electric charges or magnetic poles. Other important functions satisfying Laplace's equation are the velocity potential of the irrotational motion of an incompressible fluid, used in hydrodynamics; the steady temperature at points in a homogeneous solid, and the steady state of diffusion through a homogeneous body. The gravitational potential V at points occupied by mass of density d satisfies Poisson's equation $\partial^2V/\partial x^2 + \partial^2V/\partial y^2 + \partial^2V/\partial z^2 = -4\pi d$.

Parabolic The heat equation $\partial T/\partial t = \partial^2T/\partial x^2 + \partial^2T/\partial y^2$ represents nonequilibrium or unsteady states of heat conduction and diffusion.

Hyperbolic The wave equation $\partial^2u/\partial t^2 = c^2(\partial^2u/\partial x^2 + \partial^2u/\partial y^2)$ represents wave propagation of many varied types.

Quasilinear first-order differential equations are like

$$a\,\frac{\partial u}{\partial x} + b\,\frac{\partial u}{\partial y} = f$$

where a, b, and f depend on x, y, and u, with $a^2 + b^2 \neq 0$. This equation can be solved using the method of characteristics, which writes the solution in terms of a parameter s, which defines a path for the characteristic.

$$\frac{dx}{ds} = a, \quad \frac{dy}{ds} = b, \quad \frac{du}{ds} = f$$

These equations are integrated from some initial conditions. For a specified value of s, the value of x and y shows the location where the solution is u. The equation is semilinear if a and b depend just on x and y (and not u), and the equation is linear if a, b, and f all depend on x and y, but not u. Such equations give rise to shock propagation, and conditions have been derived to deduce the presence of shocks, Ref. 245. For further information, see Refs. 79, 159, 192, and 245.

An example of a linear hyperbolic equation is the advection equation for flow of contaminants when the x and y velocity components are u and v, respectively.

$$\frac{\partial c}{\partial t} + u\,\frac{\partial c}{\partial x} + v\,\frac{\partial c}{\partial y} = 0$$

The equations for flow and adsorption in a packed bed or chromatography column give a quasilinear equation.

$$\phi\,\frac{\partial c}{\partial t} + \phi\,u\,\frac{\partial c}{\partial x} + (1 - \phi)\,\frac{df}{dc}\,\frac{\partial c}{\partial t} = 0$$

Here $n = f(c)$ is the relation between concentration on the adsorbent and fluid concentration.

The solution of problems involving partial differential equations often revolves about an attempt to reduce the partial differential equation to one or more ordinary differential equations. The solutions of the ordinary differential equations are then combined (if possible) so that the boundary conditions as well as the original partial differential equation are simultaneously satisfied. Three of these techniques are illustrated.

Similarity Variables The physical meaning of the term "similarity" relates to internal similitude, or self-similitude. Thus, similar solutions in boundary-layer flow over a horizontal flat plate are those for which the horizontal component of velocity u has the property that two velocity profiles located at different coordinates x differ only by a scale factor. The mathematical interpretation of the term similarity is a transformation of variables carried out so that a reduction in the number of independent variables is achieved. There are essentially two methods for finding similarity variables, "separation of variables" (not the classical concept) and the use of "continuous transformation groups." The basic theory is available in Ames (see the references).

Example The equation $\partial\theta/\partial x = (A/y)(\partial^2\theta/\partial y^2)$ with the boundary conditions $\theta = 0$ at $x = 0$, $y > 0$; $\theta = 0$ at $y = \infty$, $x > 0$; $\theta = 1$ at $y = 0$, $x > 0$ represents the nondimensional temperature θ of a fluid moving past an infinitely wide flat plate immersed in the fluid. Turbulent transfer is neglected, as is molecular transport except in the y direction. It is now assumed that the equation and the boundary conditions can be satisfied by a solution of the form $\theta = f(y/x^n) = f(u)$, where $\theta = 0$ at $u = \infty$ and $\theta = 1$ at $u = 0$. The purpose here is to replace the independent variables x and y by the single variable u when it is hoped that a value of n exists which will allow x and y to be completely eliminated in the equation. In this case since $u = y/x^n$, there results after some calculation $\partial\theta/\partial x = -(nu/x)(d\theta/du)$, $\partial^2\theta/\partial y^2 = (1/x^{2n})(d^2\theta/du^2)$, and when these are substituted in the equation, $-(1/x)nu(d\theta/du) = (1/x^{3n})(A/u)(d^2\theta/du^2)$. For this to be a function of u only, choose $n = 1/3$. There results $(d^2\theta/du^2) + (u^2/3A)(d\theta/du) = 0$. Two integrations and use of the boundary conditions for this ordinary differential equation give the solution

$$\theta = \int_u^\infty \exp\,(-u^3/9A)\,du \bigg/ \int_0^\infty \exp\,(-u^3/9A)\,du$$

Group Method The type of transformation can be deduced using group theory. For a complete exposition, see Refs. 9, 12, and 145; a shortened version is in Ref. 106. Basically, a similarity transformation should be considered when one of the independent variables has no physical scale (perhaps it goes to infinity). The boundary conditions must also simplify (and combine) since each transformation leads to a differential equation with one fewer independent variable.

Example A similarity variable is found for the problem

$$\frac{\partial c}{\partial t} = \frac{\partial}{\partial x}\left(D(c)\,\frac{\partial c}{\partial x}\right), \quad c(0,t) = 1, \quad c(\infty,t) = 0, \quad c(x,0) = 0$$

Note that the length dimension goes to infinity, so that there is no length scale in the problem statement; this is a clue to try a similarity transformation. The transformation examined here is

$$\bar{t} = a^\alpha t, \quad \bar{x} = a^\beta x, \quad \bar{c} = a^\gamma c$$

With this substitution, the equation becomes

$$a^{\alpha-\gamma}\,\frac{\partial \bar{c}}{\partial \bar{t}} = a^{2\beta-\gamma}\,\frac{\partial}{\partial \bar{x}}\left[D(a^{-\gamma}\bar{c})\,\frac{\partial \bar{c}}{\partial \bar{x}}\right]$$

Group theory says a system is conformally invariant if it has the same form in the new variables; here, that is

$$\gamma = 0, \quad \alpha - \gamma = 2\beta - \gamma, \quad \text{or } \alpha = 2\beta$$

The invariants are

$$\eta = \frac{x}{t^\delta}, \quad \delta = \frac{\beta}{\alpha}$$

and the solution is

$$c(x, t) = f(\eta)t^{\gamma/\alpha}$$

We can take $\gamma = 0$ and $\delta = \beta/\alpha = 1/2$. Note that the boundary conditions combine because the point $x = \infty$ and $t = 0$ give the same value of η and the conditions on c at $x = \infty$ and $t = 0$ are the same. We thus make the transformation

$$\eta = \frac{x}{\sqrt{4D_0 t}}, \quad c(x, t) = f(\eta)$$

The use of the 4 and D_0 makes the analysis below simpler. The result is

$$\frac{d}{d\eta}\left[D(c)\,\frac{df}{d\eta}\right] + 2\eta\,\frac{df}{d\eta} = 0, \quad f(0) = 1, \quad f(\infty) = 0$$

Thus, we solve a two-point boundary value problem instead of a partial differential equation. When the diffusivity is constant, the solution is the error function, a tabulated function.

$$c(x,t) = 1 - \text{erf}\,\eta = \text{erfc}\,\eta$$

$$\text{erf}\,\eta = \int_0^\eta e^{-\xi^2}\,d\xi \bigg/ \int_0^\infty e^{-\xi^2}\,d\xi$$

Separation of Variables This is a powerful, well-utilized method which is applicable in certain circumstances. It consists of assuming that the solution for a partial differential equation has the form $U = f(x)g(y)$. If it is then possible to obtain an ordinary differential equation on one side of the equation depending only on x and on the other side only on y, the partial differential equation is said to be separable in the variables x, y. If this is the case, one side of the equation is a function of x alone and the other of y alone. The two can be equal only if each is a constant, say λ. Thus the problem has again been reduced to the solution of ordinary differential equations.

Example Laplace's equation $\partial^2V/\partial x^2 + \partial^2V/\partial y^2 = 0$ plus the boundary conditions $V(0, y) = 0$, $V(l, y) = 0$, $V(x, \infty) = 0$, $V(x, 0) = f(x)$ represents the steady-state potential in a thin plate (in z direction) of infinite extent in the y direction

Copyright © 1999 by The McGraw-Hill Companies, Inc. All rights reserved. Use of this product is subject to the terms of its license agreement. Click here to view.

and of width l in the x direction. A potential $f(x)$ is impressed (at $y = 0$) from $x = 0$ to $x = 1$, and the sides are grounded. To obtain a solution of this boundary-value problem assume $V(x, y) = f(x)g(y)$. Substitution in the differential equation yields $f''(x)g(y) + f(x)g''(y) = 0$, or $g''(y)/g(y) = -f''(x)/f(x) = \lambda^2$ (say). This system becomes $g''(y) - \lambda^2 g(y) = 0$ and $f''(x) + \lambda^2 f(x) = 0$. The solutions of these ordinary differential equations are respectively $g(y) = Ae^{\lambda y} + Be^{-\lambda y}$, $f(x) = C \sin \lambda x + D \cos \lambda x$. Then $f(x)g(y) = (Ae^{\lambda y} + Be^{-\lambda y})(C \sin \lambda x + D \cos \lambda x)$. Now $V(0, y) = 0$ so that $f(0)g(y) = (Ae^{\lambda y} + Be^{-\lambda y}) D \equiv 0$ for all y. Hence $D = 0$. The solution then has the form $\sin \lambda x\, (Ae^{\lambda y} + Be^{-\lambda y})$ where the multiplicative constant C has been eliminated. Since $V(l, y) = 0$, $\sin \lambda l (Ae^{\lambda y} + Be^{-\lambda y}) \equiv 0$. Clearly the bracketed function of y is not zero, for the solution would then be the identically zero solution. Hence $\sin \lambda l = 0$ or $\lambda_n = n\pi/l$, $n = 1, 2, \ldots$ where $\lambda_n = n$th eigenvalue.

The solution now has the form $\sin (n\pi x/l)(Ae^{n\pi y/l} + Be^{-n\pi y/l})$. Since $V(x, \infty) = 0$, A must be taken to be zero because e^y becomes arbitrarily large as $y \to \infty$. The solution then reads $B_n \sin (n\pi x/l)e^{-n\pi y/l}$, where B_n is the multiplicative constant. The differential equation is linear and homogeneous so that $\sum_{n=1}^{\infty} B_n e^{-n\pi y/l} \sin (n\pi x/l)$ is also a solution. Satisfaction of the last boundary condition is ensured by taking

$$B_n = \frac{2}{l}\int_0^l f(x) \sin (n\pi x/l)\, dx = \text{Fourier sine coefficients of } f(x)$$

Further, convergence and differentiability of this series are established quite easily. Thus the solution is

$$V(x, y) = \sum_{n=1}^{\infty} B_n e^{-n\pi y/l} \sin \frac{n\pi x}{l}$$

Example The diffusion problem

$$\frac{\partial c}{\partial t} = \frac{\partial}{\partial x}\left(D(c)\frac{\partial c}{\partial x}\right), \quad c(0, t) = 1, \quad c(\infty, t) = 0, \quad c(x, 0) = 0$$

can be solved by separation of variables. First transform the problem so that the boundary conditions are homogeneous (having zeroes on the right-hand side). Let

$$c(x, t) = 1 - x + u(x, t)$$

Then $u(x, t)$ satisfies

$$\frac{\partial u}{\partial t} = D\frac{\partial^2 u}{\partial x^2}, \quad u(x, 0) = x - 1, \quad u(0, t) = 0, \quad u(1, t) = 0$$

Assume a solution of the form $u(x, t) = X(x)\, T(t)$, which gives

$$X\frac{dT}{dt} = D\, T\frac{d^2X}{dx^2}$$

Since both sides are constant, this gives the following ordinary differential equations to solve.

$$\frac{1}{D\,T}\frac{dT}{dt} = -\lambda, \quad \frac{1}{X}\frac{d^2X}{dx^2} = -\lambda$$

The solution of these is

$$T = A\, e^{-\lambda Dt}, \quad X = B \cos \sqrt{\lambda}\, x + E \sin \sqrt{\lambda}\, x$$

The combined solution for $u(x,t)$ is

$$u = A\,(B \cos \sqrt{\lambda}\, x + E \sin \sqrt{\lambda}\, x)\, e^{-\lambda Dt}$$

Apply the boundary condition that $u(0,t) = 0$ to give $B = 0$. Then the solution is

$$u = A\,(\sin \sqrt{\lambda}\, x)e^{-\lambda Dt}$$

where the multiplicative constant E has been eliminated. Apply the boundary condition at $x = L$.

$$0 = A\,(\sin \sqrt{\lambda}\, L)e^{-\lambda Dt}$$

This can be satisfied by choosing $A = 0$, which gives no solution. However, it can also be satisfied by choosing λ such that

$$\sin \sqrt{\lambda}\, L = 0, \quad \sqrt{\lambda}\, L = n\,\pi$$

Thus

$$\lambda = \frac{n^2\pi^2}{L^2}$$

The combined solution can now be written as

$$u = A\left(\frac{\sin n\pi x}{L}\right)e^{-n^2\pi^2 Dt/L^2}$$

Since the initial condition must be satisfied, we use an infinite series of these functions.

$$u = \sum_{n=1}^{\infty} A_n\left(\frac{\sin n\pi x}{L}\right)e^{-n^2\pi^2 Dt/L^2}$$

At $t = 0$, we satisfy the initial condition.

$$x - 1 = \sum_{n=1}^{\infty} A_n\left(\frac{\sin n\pi x}{L}\right)$$

This is done by multiplying the equation by

$$\frac{\sin m\pi x}{L}$$

and integrating over x: $0 \to L$. (This is the same as minimizing the mean-square error of the initial condition.) This gives

$$\frac{A_m L}{2} = \int_0^L (x - 1) \sin m\pi x\, dx$$

which completes the solution.

Integral-Transform Method A number of integral transforms are used in the solution of differential equations. Only one, the Laplace transform, will be discussed here [for others, see "Integral Transforms (Operational Methods)"]. The one-sided Laplace transform indicated by $L[f(t)]$ is defined by the equation $L[f(t)] = \int_0^{\infty} f(t)e^{-st}\, dt$. It has numerous important properties. The ones of interest here are $L[f'(t)] = sL[f(t)] - f(0)$; $L[f''(t)] = s^2L[f(t)] - sf(0) - f'(0)$; $L[f^{(n)}(t)] = s^nL[f(t)] - s^{n-1}f(0) - s^{n-2}f'(0) - \cdots - f^{(n-1)}(0)$ for ordinary derivatives. For partial derivatives an indication of which variable is being transformed avoids confusion. Thus, if

$$y = y(x, t), \quad L_t\left[\frac{\partial y}{\partial t}\right] = sL[y(x, t)] - y(x, 0)$$

whereas

$$L_t\left[\frac{\partial y}{\partial x}\right] = \frac{dL_t[y(x, t)]}{dx}$$

since $L[y(x, t)]$ is "really" only a function of x. Otherwise the results are similar. These facts coupled with the linearity of the transform, i.e., $L[af(t) + bg(t)] = aL[f(t)] + bL[g(t)]$, make it a useful device in solving some linear differential equations. Its use reduces the solution of ordinary differential equations to the solution of algebraic equations for $L[y]$. The solution of partial differential equations is reduced to the solution of ordinary differential equations. In both situations the inverse transform must be obtained either from tables, of which there are several, or by use of complex inversion methods.

Example The equation $\partial c/\partial t = D(\partial^2 c/\partial x^2)$ represents the diffusion in a semi-infinite medium, $x \geq 0$. Under the boundary conditions $c(0, t) = c_0$, $c(x, 0) = 0$ find a solution of the diffusion equation. By taking the Laplace transform of both sides with respect to t,

$$\int_0^{\infty} e^{-st}\frac{\partial^2 c}{\partial x^2}\, dt = \frac{1}{D}\int_0^{\infty} e^{-st}\frac{\partial c}{\partial t}\, dt$$

or

$$\frac{d^2F}{dx^2} = (1/D)sF - c(x, 0) = \frac{sF}{D}$$

where $F(x, s) = L_t[c(x, t)]$. Hence

$$\frac{d^2F}{dx^2} - \left(\frac{s}{D}\right)F = 0$$

The other boundary condition transforms into $F(0, s) = c_0/s$. Finally the solution of the ordinary differential equation for F subject to $F(0, s) = c_0/s$ and F remains finite as $x \to \infty$ is $F(x, s) = (c_0/s)e^{-\sqrt{s/D}x}$. Reference to a table shows that the function having this as its Laplace transform is

$$c(x, t) = c_0\left[1 - \frac{2}{\sqrt{\pi}}\int_0^{x/2\sqrt{Dt}} e^{-u^2}\, du\right]$$

Matched-Asymptotic Expansions Sometimes the coefficient in front of the highest derivative is a small number. Special perturbation techniques can then be used, provided the proper scaling laws are found. See Refs. 32, 170, and 180.

DIFFERENCE EQUATIONS

References: 30, 43.

Certain situations are such that the independent variable does not vary continuously but has meaning only for discrete values. Typical illustrations occur in the stagewise processes found in chemical engineering such as distillation, staged extraction systems, and absorption columns. In each of these the operation is characterized by a finite between-stage change of the dependent variable in which the independent variable is the integral number of the stage. The importance of difference equations is twofold: (1) to analyze problems of the type described and (2) to obtain approximate solutions of problems which lead, in their formulation, to differential equations. In this subsection only problems of analysis are considered; the application to approximate solutions is considered under "Numerical Analysis and Approximate Methods."

ELEMENTS OF THE CALCULUS OF FINITE DIFFERENCES

Let $y = f(x)$ be defined for discrete equidistant values of x, which will be denoted by x_n. The corresponding value of y will be written $y_n = f(x_n)$. The first forward difference of $f(x)$ denoted by $\Delta f(x) = f(x + h) - f(x)$ where $h = x_n - x_{n-1}$ = interval length.

Example Let $f(x) = x^2$. Then $\Delta f(x) = (x + h)^2 - x^2 = 2hx + h^2$.

The second forward difference is obtained by taking the difference of the first; thus $\Delta\Delta f(x) = \Delta^2 f(x) = \Delta f(x + h) - \Delta f(x) = f(x + 2h) - 2f(x + h) + f(x)$.

Example $f(x) = x^2$, $\Delta^2 f(x) = \Delta[\Delta f(x)] = \Delta 2hx + \Delta h^2 = 2h(x + h) - 2hx + h^2 - h^2 = 2h^2$.

Similarly the nth forward difference is defined by the relation $\Delta^n f(x) = \Delta[\Delta^{n-1} f(x)]$. Other difference relations are also quite useful. Some of these are $\nabla f(x) = f(x) - f(x - h)$, which is called the backward difference, and $\delta f(x) = f[x + (h/2)] - f[x - (h/2)]$, called the central difference. Some properties of the operator Δ are quite important. If C is any constant, $\Delta C = 0$; if $f(x)$ is any function of period h, $\Delta f(x) = 0$ (in fact, periodic functions of period h play the same role here as constants do in the differential calculus); $\Delta[f(x) + g(x)] = \Delta f(x) + \Delta g(x)$; $\Delta^m[\Delta^n f(x)] = \Delta^{m+n} f(x)$; $\Delta[f(x)g(x)] = f(x)\,\Delta g(x) + g(x + h)\,\Delta f(x)$

$$\Delta\left[\frac{f(x)}{g(x)}\right] = \frac{g(x)\,\Delta f(x) - f(x)\,\Delta g(x)}{g(x)g(x + h)}$$

Example $\Delta(x \sin x) = x\Delta \sin x + \sin(x + h)\,\Delta x = 2x \sin(h/2) \cos[x + (h/2)] + h \sin(x + h)$.

DIFFERENCE EQUATIONS

A difference equation is a relation between the differences and the independent variable, $\phi(\Delta^n y, \Delta^{n-1} y, \ldots, \Delta y, y, x) = 0$, where ϕ is some given function. The general case in which the interval between the successive points is any real number h, instead of 1, can be reduced to that with interval size 1 by the substitution $x = hx'$. Hence all further difference-equation work will assume the interval size between successive points is 1.

Example $f(x + 1) - (\alpha + 1)f(x) + \alpha f(x - 1) = 0$. Common notation usually is $y_x = f(x)$. This equation is then written $y_{x+1} - (\alpha + 1)y_x + \alpha y_{x-1} = 0$.

Example $y_{x+2} + 2y_x y_{x+1} + y_x = x^2$.

Example $y_{x+1} - y_x = 2^x$.

The order of the difference equation is the difference between the largest and smallest arguments when written in the form of the second example. The first and second examples are both of order 2, while the third example is of order 1. A linear difference equation involves no products or other nonlinear functions of the dependent variable and its differences. The first and third examples are linear, while the second example is nonlinear.

A solution of a difference equation is a relation between the variables which satisfies the equation. If the difference equation is of order n, the general solution involves n arbitrary constants. The techniques for solving difference equations resemble techniques used for differential equations.

Equation $\Delta^n y = a$ The solution of $\Delta^n y = a$, where a is a constant, is a polynomial of degree n plus an arbitrary periodic function of period 1. That is, $y = (ax^n/n!) + c_1 x^{n-1} + c_2 x^{n-2} + \cdots + c_n + f(x)$, where $f(x + 1) = f(x)$.

Example $\Delta^3 y = 6$. The solution is $y = x^3 + c_1 x^2 + c_2 x + c_3 + f(x)$; c_1, c_2, c_3 are arbitrary constants, and $f(x)$ is an arbitrary periodic function of period 1.

Equation $y_{x+1} - y_x = \phi(x)$ This equation states that the first difference of the unknown function is equal to the given function $\phi(x)$. The solution by analogy with solving the differential equation $dy/dx = \phi(x)$ by integration is obtained by "finite integration" or summation. When there are only a finite number of data points, this is easily accomplished by writing $y_x = y_0 + \sum_{t=1}^{x} \phi(t - 1)$, where the data points are numbered from 1 to x. This is the only situation considered here.

Examples If $\phi(x) = 1$, $y_x = x$. If $\phi(x) = x$, $y_x = [x(x - 1)]/2$. If $\phi(x) = a^x$, $a \neq 0$, $y_x = a^x/(a - 1)$. In all cases $y_0 = 0$.

Other examples may be evaluated by using summation, that is, $y_2 = y_1 + \phi(1)$, $y_3 = y_2 + \phi(2) = y_1 + \phi(1) + \phi(2)$, $y_4 = y_3 + \phi(3) = y_1 + \phi(1) + \phi(2) + \phi(3), \ldots, y_x = y_1 + \sum_{t=1}^{x-1} \phi(t)$.

Example $y_{x+1} - ry_x = 1$, r constant, $x > 0$ and $y_0 = 1$. $y_1 = 1 + r$, $y_2 = 1 + r + r^2, \ldots, y_x = 1 + r + \cdots + r^x = (1 - r^{x+1})/(1 - r)$ for $r \neq 1$ and $y_x = 1 + x$ for $r = 1$.

Linear Difference Equations The linear difference equation of order n has the form $P_n y_{x+n} + P_{n-1} y_{x+n-1} + \cdots + P_1 y_{x+1} + P_0 y_x = Q(x)$ with $P_n \neq 0$ and $P_0 \neq 0$ and P_j; $j = 0, \ldots, n$ are functions of x.

Constant Coefficient and* Q(x) = *0 (Homogeneous) The solution is obtained by trying a solution of the form $y_x = c\beta^x$. When this trial solution is substituted in the difference equation, a polynomial of degree n results for β. If the solutions of this polynomial are denoted by $\beta_1, \beta_2, \ldots, \beta_n$ then the following cases result: (1) if all the β_j's are real and unequal, the solution is $y_x = \sum_{j=1}^{n} c_j \beta_j^x$, where the $c_1, \ldots, c_n$ are arbitrary constants; (2) if the roots are real and repeated, say, β_j has multiplicity m, then the partial solution corresponding to β_j is $\beta_j^x(c_1 + c_2 x + \cdots + c_m x^{m-1})$; (3) if the roots are complex conjugates, say, $a + ib = pe^{i\theta}$ and $a - ib = pe^{-i\theta}$, the partial solution corresponding to this pair is $p^x(c_1 \cos \theta x + c_2 \sin \theta x)$; and (4) if the roots are multiple complex conjugates, say, $a + ib = pe^{i\theta}$ and $a - ib = pe^{-i\theta}$ are m-fold, then the partial solution corresponding to these is $p^x[(c_1 + c_2 x + \cdots + c_m x^{m-1}) \cos \theta x + (d_1 + d_2 x + \cdots + d_m x^{m-1}) \sin \theta x]$.

Example The equation $y_{x+1} - (\alpha + 1)y_x + \alpha y_{x-1} = 0$, $y_0 = c_0$ and $y_{m+1} = x_{m+1}/k$ represents the steady-state composition of transferable material in the raffinate stream of a staged countercurrent liquid-liquid extraction system. Clearly y is a function of the stage number x. α is a combination of system constants. By using the trial solution $y_x = c\beta^x$, there results $\beta^2 - (\alpha + 1)\beta + \alpha = 0$, so that $\beta_1 = 1$, $\beta_2 = \alpha$. The general solution is $y_x = c_1 + c_2\alpha^x$. By using the side conditions, $c_1 = c_0 - c_2$, $c_2 = (y_{m+1} - c_0)/(\alpha^{m+1} - 1)$. The desired solution is $(y_x - c_0)/(y_{m+1} - c_0) = (\alpha^x - 1)/(\alpha^{m+1} - 1)$.

Example $y_{x+3} - 3y_{x+2} + 4y_x = 0$. By setting $y_x = c\beta^x$, there results $\beta^3 - 3\beta^2 + 4 = 0$ or $\beta_1 = -1$, $\beta_2 = 2$, $\beta_3 = 2$. The general solution is $y_x = c_1(-1)^x + 2^x(c_2 + c_3 x)$.

Example $y_{x+1} - 2y_x + 2y_{x-1} = 0$. $\beta_1 = 1 + i$, $\beta_2 = 1 - i$. $p = \sqrt{1 + 1} = \sqrt{2}$, $\theta = \pi/4$. The solution is $y_x = 2^{x/2}[c_1 \cos(x\pi/4) + c_2 \sin(x\pi/4)]$.

Constant Coefficients and* Q(x) ≠ *0 (Nonhomogeneous) In this case the general solution is found by first obtaining the homoge-

neous solution, say, y_x^H and adding to it any particular solution with $Q(x) \neq 0$, say, y_x^P. There are several means of obtaining the particular solution.

Method of Undetermined Coefficients If $Q(x)$ is a product or linear combination of products of the functions e^{bx}, a^x, x^p (p a positive integer or zero) $\cos cx$ and $\sin cx$, this method may be used. The "families" $[a^x]$, $[e^{bx}]$, $[\sin cx, \cos cx]$ and $[x^p, x^{p-1}, \ldots, x, 1]$ are defined for each of the above functions in the following way: The family of a term f_x is the set of all functions of which f_x and all operations of the form a^{x+y}, $\cos c(x+y)$, $\sin c(x+y)$, $(x+y)^p$ on f_x and their linear combinations result in. The technique involves the following steps: (1) Solve the homogeneous system. (2) Construct the family of each term. (3) If the family has no representative in the homogeneous solution, assume y_x^P is a linear combination of the families of each term and determine the constants so that the equation is satisfied. (4) If a family has a representative in the homogeneous solution, multiply each member of the family by the smallest integral power of x for which all such representatives are removed and revert to step 3.

Example $y_{x+1} - 3y_x + 2y_{x-1} = 1 + a^x$. $a \neq 0$. The homogeneous solution is $y_x^H = c_1 + c_2 2^x$. The family of 1 is 1 and of a^x is a^x. However, 1 is a solution of the homogeneous system. Therefore, try $y_x^P = Ax + Ba^x$. Substituting in the equation there results

$$y_x = c_1 + c_2 2^x - x + \frac{a}{(a-1)(a-2)} a^x \quad a \neq 1,\ a \neq 2$$

If $a = 1$, $y_x = c_1 + c_2 2^x - 2x$. If $a = 2$, $y_x = c_1 + c_2 2^x - x + x2^x$.

Example The family of $x^2 3^x$ is $[x^2 3^x, x3^x, 3^x]$.

Method of Variation of Parameters This technique is applicable to general linear difference equations. It is illustrated for the second-order system $y_{x+2} + Ay_{x+1} + By_x = \phi(x)$. Assume that the homogeneous solution has been found by some technique and write $y_x^H = c_1 u_x + c_2 v_x$. Assume that a particular solution $y_x^P = D_x u_x + E_x v_x$. E_x and D_x can be found by solving the equations:

$$E_{x+1} - E_x = \frac{u_{x+1}\phi(x)}{u_{x+1}v_{x+2} - u_{x+2}v_{x+1}}$$

$$D_{x+1} - D_x = \frac{v_{x+1}\phi(x)}{v_{x+1}u_{x+2} - v_{x+2}u_{x+1}}$$

by summation. The general solution is then $y_x = y_x^P + y_x^H$.

Variable Coefficients The method of variation of parameters applies equally well to the linear difference equation with variable coefficients. Techniques are therefore needed to solve the homogeneous system with variable coefficients.

Equation $y_{x+1} - a_x y_x = 0$ By assuming that this equation is valid for $x \geq 0$ and $y_0 = c$, the solution is $y_x = c \prod_{n=1}^{x} a_{n-1}$.

Example $y_{x+1} + \dfrac{x+2}{x+1} y_x = 0$. The solution is

$$y_x = c \prod_{n=1}^{x} \left(-\frac{n+1}{n}\right) = c(-1)^x \frac{2}{1} \cdot \frac{3}{2} \cdots \frac{x+1}{x} = (-1)^x c(x+1)$$

Example $y_{x+1} - xy_x = 0$. The solution is $y_x = c(x-1)!$

Reduction of Order If one homogeneous solution, say, u_x, can be found by inspection or otherwise, an equation of lower order can be obtained by the substitution $v_x = y_x/u_x$. The resultant equation must be satisfied by v_x = constant or $\Delta v_x = 0$. Thus the equation will be of reduced order if the new variable $U_x = \Delta(y_x/u_x)$ is introduced.

Example $(x+2)y_{x+2} - (x+3)y_{x+1} + y_x = 0$. By observation $u_x = 1$ is a solution. Set $U_x = \Delta y_x = y_{x+1} - y_x$. There results $(x+2)U_{x+1} - U_x = 0$, which is of degree one lower than the original equation. The complete solution for y_x is finally

$$y_x = c_0 \sum_{n=0}^{x} \frac{1}{n!} + c_1$$

Factorization If the difference equation can be factored, then the general solution can be obtained by solving two or more successive equations of lower order. Consider $y_{x+2} + A_x y_{x+1} + B_x y_x = \phi(x)$. If there exists a_x, b_x such that $a_x + b_x = -A_x$ and $a_x b_x = B_x$, then the difference equation may be written $y_{x+2} - (a_x + b_x)\, y_{x+1} + a_x b_x y_x = \phi(x)$. First solve $U_{x+1} - b_x U_x = \phi(x)$ and then $y_{x+1} - a_x y_x = U_x$.

Example $y_{x+2} - (2x+1)y_{x+1} + (x^2+x)y_x = 0$. Set $a_x = x$, $b_x = x+1$. Solve $u_{x+1} - (x+1)u_x = 0$ and then $y_{x+1} - xy_x = u_x$.

Substitution If it is possible to rearrange a difference equation so that it takes the form $af_{x+2}y_{x+2} + bf_{x+1}y_{x+1} + cf_x y_x = \phi(x)$ with a, b, c constants, then the substitution $u_x = f_x y_x$ reduces the equation to one with constant coefficients.

Example $(x+2)^2 y_{x+2} - 3(x+1)^2 y_{x+1} + 2x^2 y_x = 0$. Set $u_x = x^2 y_x$. The equation becomes $u_{x+2} - 3u_{x+1} + 2u_x = 0$, which is linear and easily solved by previous methods.

The substitution $u_x = y_x/f_x$ reduces $af_x f_{x+1} y_{x+z} + bf_x f_{x+2} y_{x+1} + cf_{x+1} f_{x+2} y_x = \phi(x)$ to an equation with constant coefficients.

Example $x(x+1)y_{x+2} + 3x(x+2)y_{x+1} - 4(x+1)(x+2)y_x = x$. Set $u_x = y_x/f_x = y_x/x$. Then $y_x = xu_x$, $y_{x+1} = (x+1)u_{x+1}$ and $y_{x+2} = (x+2)u_{x+2}$. Substitution in the equation yields $x(x+1)(x+2)u_{x+2} + 3x(x+2)(x+1)u_{u+1} - 4x(x+1)(x+2)u_x = x$ or $u_{x+2} + 3u_{x+1} - 4u_x = 1/(x+1)(x+2)$, which is a linear equation with constant coefficients.

Nonlinear Difference Equations: Riccati Difference Equation The Riccati equation $y_{x+1}y_x + ay_{x+1} + by_x + c = 0$ is a nonlinear difference equation which can be solved by reduction to linear form. Set $y = z + h$. The equation becomes $z_{x+1}z_x + (h+a)z_{x+1} + (h+b)z_x + h^2 + (a+b)h + c = 0$. If h is selected as a root of $h^2 + (a+b)h + c = 0$ and the equation is divided by $z_{x+1}z_x$ there results $[(h+b)/z_{x+1}] + [(h+a)/z_x] + 1 = 0$. This is a linear equation with constant coefficients. The solution is

$$y_x = h + \frac{1}{c\left[-\dfrac{a+h}{b+h}\right]^x - \dfrac{1}{(a+h)+(b+h)}}$$

Example This equation is obtained in distillation problems, among others, in which the number of theoretical plates is required. If the relative volatility is assumed to be constant, the plates are theoretically perfect, and the molal liquid and vapor rates are constant, then a material balance around the nth plate of the enriching section yields a Riccati difference equation.

INTEGRAL EQUATIONS

REFERENCES: 75, 79, 105, 195, 273. See also "Numerical Analysis and Approximate Methods."

An integral equation is any equation in which the unknown function appears under the sign of integration and possibly outside the sign of integration. If derivatives of the dependent variable appear elsewhere in the equation, the equation is said to be integrodifferential.

CLASSIFICATION OF INTEGRAL EQUATIONS

Volterra integral equations have an integral with a variable limit. The Volterra equation of the second kind is

$$u(x) = f(x) + \lambda \int_a^x K(x, t)u(t)\, dt$$
